Executive Summary

This report presents an assessment of the water-supply potential of the Anderson Valley in southwest Clinton County. The Anderson Valley is a large pre-glacial valley carved into the bedrock in central Indiana. The valley, relatively unexplored for water-supply potential, was identified in the Central Indiana Water Study as a potential regional water source for an area of the state where new sources of water will likely be needed to meet future demand (INTERA, 2021).

The goal of the project was to characterize the occurrence, geometry, and hydraulic properties of permeable sediments within the Valley, and to assess the potential for a high-capacity groundwater supply. To accomplish this, an exploratory boring and aquifer testing program was conducted in a portion of the Anderson Valley southwest of the City of Frankfort. The data gathered from the testing program was used to create a 3D conceptual geologic model (CGM) of the area which was, in turn, used to develop a conceptual groundwater model. A transient groundwater model was then used to estimate yields of hypothetical well fields in the study area.

The focus of this study was an approximately 20 square mile area located along the I-65 corridor between Indianapolis and Lafayette, southwest of Frankfort and northeast of Colfax in Clinton County. This area is a strategic geographic location for a regional well field. Within the study area, the thickness of the unconsolidated deposits range from approximately 250 to 400 feet and consists of clay and silt-rich till interbedded with locally discontinuous but regionally extensive layers of sand and gravel. In general, the aquifer system can be separated into a shallow and a deep aquifer.

A sonic rig drilled twenty-two (22) exploratory boreholes on seven (7) sites, named: A6, C1, C2, D3, J3, N1, and M1. Lithologic core samples at all sites were logged and characterized. Eleven (11) of the boreholes were converted into monitoring wells to deploy data logging probes and collect water-quality samples. Additionally, two 8-inch diameter production wells were constructed and each tested with a 72-hour aquifer test at site J3. Water-quality sampling and analysis was conducted at monitoring wells and the two test wells to identify potential treatment concerns.

The overall goal of the project was to quantify potential yields from development of the aquifer within the study area. However, after the aquifer testing at site J3 was complete, this project was discontinued due to the relatively high price of transmission of water from the sites. It was concluded that, due to the geographic spread of the potential well fields, an extensive network of transmission mains would be necessary to develop the aquifer. The high infrastructure costs of the transmission mains made well field development impractical at this time.

The drilling and testing that occurred before project termination provided valuable geologic and hydrogeologic data. The results from the field investigation and data analysis show the following:

1. Groundwater modeling scenarios indicate that the site that was tested (J3) could produce approximately 2.0 million gallons per day [MGD] with 3 properly spaced wells. It is expected that other sites would produce similar yields, however, further field testing would be required.
2. Water-quality results show high iron and manganese in all the wells that were sampled. In addition, two of the deeper samples show high arsenic concentrations. These water-quality results are consistent with the quality found in other regional wells such as the City of Frankfort Wells. Groundwater produced in this area will require treatment.
3. On a regional scale, the Anderson Valley consists of a shallow and deep aquifer, however, the geologic model indicates, and the exploratory drilling and pumping data confirm that locally, there is spatial variability in the presence and continuity of the two regionally extensive aquifer layers.
4. The results of the study show that, within the study area, the Anderson Valley has potential for high-capacity well field development to accommodate growth in the region. Water resource development would be of tremendous value to Clinton County and it's residents.

1 Introduction

The Anderson Valley is a large pre-glacial valley carved into the bedrock through central Indiana. The bedrock valley was identified in the Central Indiana Water Study as a potential regional water source for an area of the state where new sources of water may be needed to meet future demand (INTERA, 2021). Many of the highest yielding aquifers in Indiana are buried valley aquifers, formed when glacial deposits filled in previously exposed bedrock valleys. This report presents the results of an assessment of the water supply potential of the Anderson Valley as a source of water in Clinton County.

The scope of the assessment was focused on test borings, water-quality sampling, hydraulic testing, 3D geologic modeling, and groundwater flow modeling. The objective of the project was to collect high-resolution data in order to characterize the occurrence and geometry of aquifer layers and the potential to sustainably produce raw water for public supply.

1.1 Central Indiana Water Study

The Indiana Finance Authority (IFA) recently completed the Central Indiana Water Study as part of the authority's directive to identify regional water infrastructure needs and solutions within the state (INTERA, 2021). The objective of the study was to better understand the current and future demand for water and the ability of the resource to support growth in a nine county region in the central part of the state. Areas within the nine county region where future demand may exceed available local supplies were identified. A key finding of the study was that an additional 50 million gallons per day (MGD) of water will be needed by 2070 for public water systems, with growth expected to be the highest in Hamilton County and the north side of Marion County. Demand may exceed available supplies by 2070 on the north side of the nine-county region, especially in Boone and Hamilton Counties. The section of the Anderson Valley that traverses Clinton County just north of Boone County was identified in the study as a relatively unexplored buried valley aquifer with the potential to be developed as a regional source.

1.2 The Anderson Bedrock Valley

The Anderson Bedrock Valley is the remnants of an ancient pre-glacial tributary of the Teays River. The Anderson Valley begins as a deep and narrow channel east of Madison County where it meanders west, through the center of Madison County to the north edge of Hamilton County. The bedrock valley drastically broadens on the north edge of Boone County as it traverses Clinton County, eventually connecting to the Teays Bedrock Valley a few miles west of Lafayette, IN (Figure 1). This broad, lower section of the valley in Clinton County has been referred to as the Frankfort Lowland Section, due to the proximity of Frankfort, Indiana (Bleuer, 1991). The high energy environment in the the broad lower section of the Anderson Valley conveyed glacial outwash material, resulting in permeable layers of sand and gravel

(Wayne, 1956).

1.3 Study Area

The focus of this study was an approximate 20 square mile area located along the I-65 corridor between Indianapolis and Lafayette, southwest of Frankfort in Clinton County (Figure 1). This area sits within the footprint of the Anderson Bedrock Valley and is a strategic geographic location for a regional well field. Within the Study Area, the thickness of the unconsolidated deposits range in thickness from 425 to 179 ft, and consists predominately of clay and silt-rich till interbedded with regionally discontinuous zones of sand and gravel.

2 City of Frankfort Municipal Wells

The City of Frankfort's Municipal Utility operates a well field within the Anderson Valley, located on the west side of the city, with seven production wells registered as a high-capacity wells with the Indiana Department of Natural Resources (IDNR) Significant Water Withdrawal Database (SWWF) (IDNR, 2022).

The production wells pump from two distinct confined layers of sand and gravel separated by a significant layer of glacial till. Production Wells 16, 22, and 23 are screened within a relatively shallow zone (Shallow Aquifer), have rated capacities ranging from 600-1200 gallons per minute (gpm), are 10 to 24 inches in diameter, and range from 93 to 105 ft deep. Production Wells 17, 19, 20, and 21 are screened within a deeper layer (Deep Aquifer), have rated capacities ranging from 500 to 1200 gpm, are 12 to 20 inches in diameter, and are 276 to 302 ft deep. Reported annual pumpage from the wells averaged approximately 3.3 MGD between 2019-2021 (IDNR, 2022).

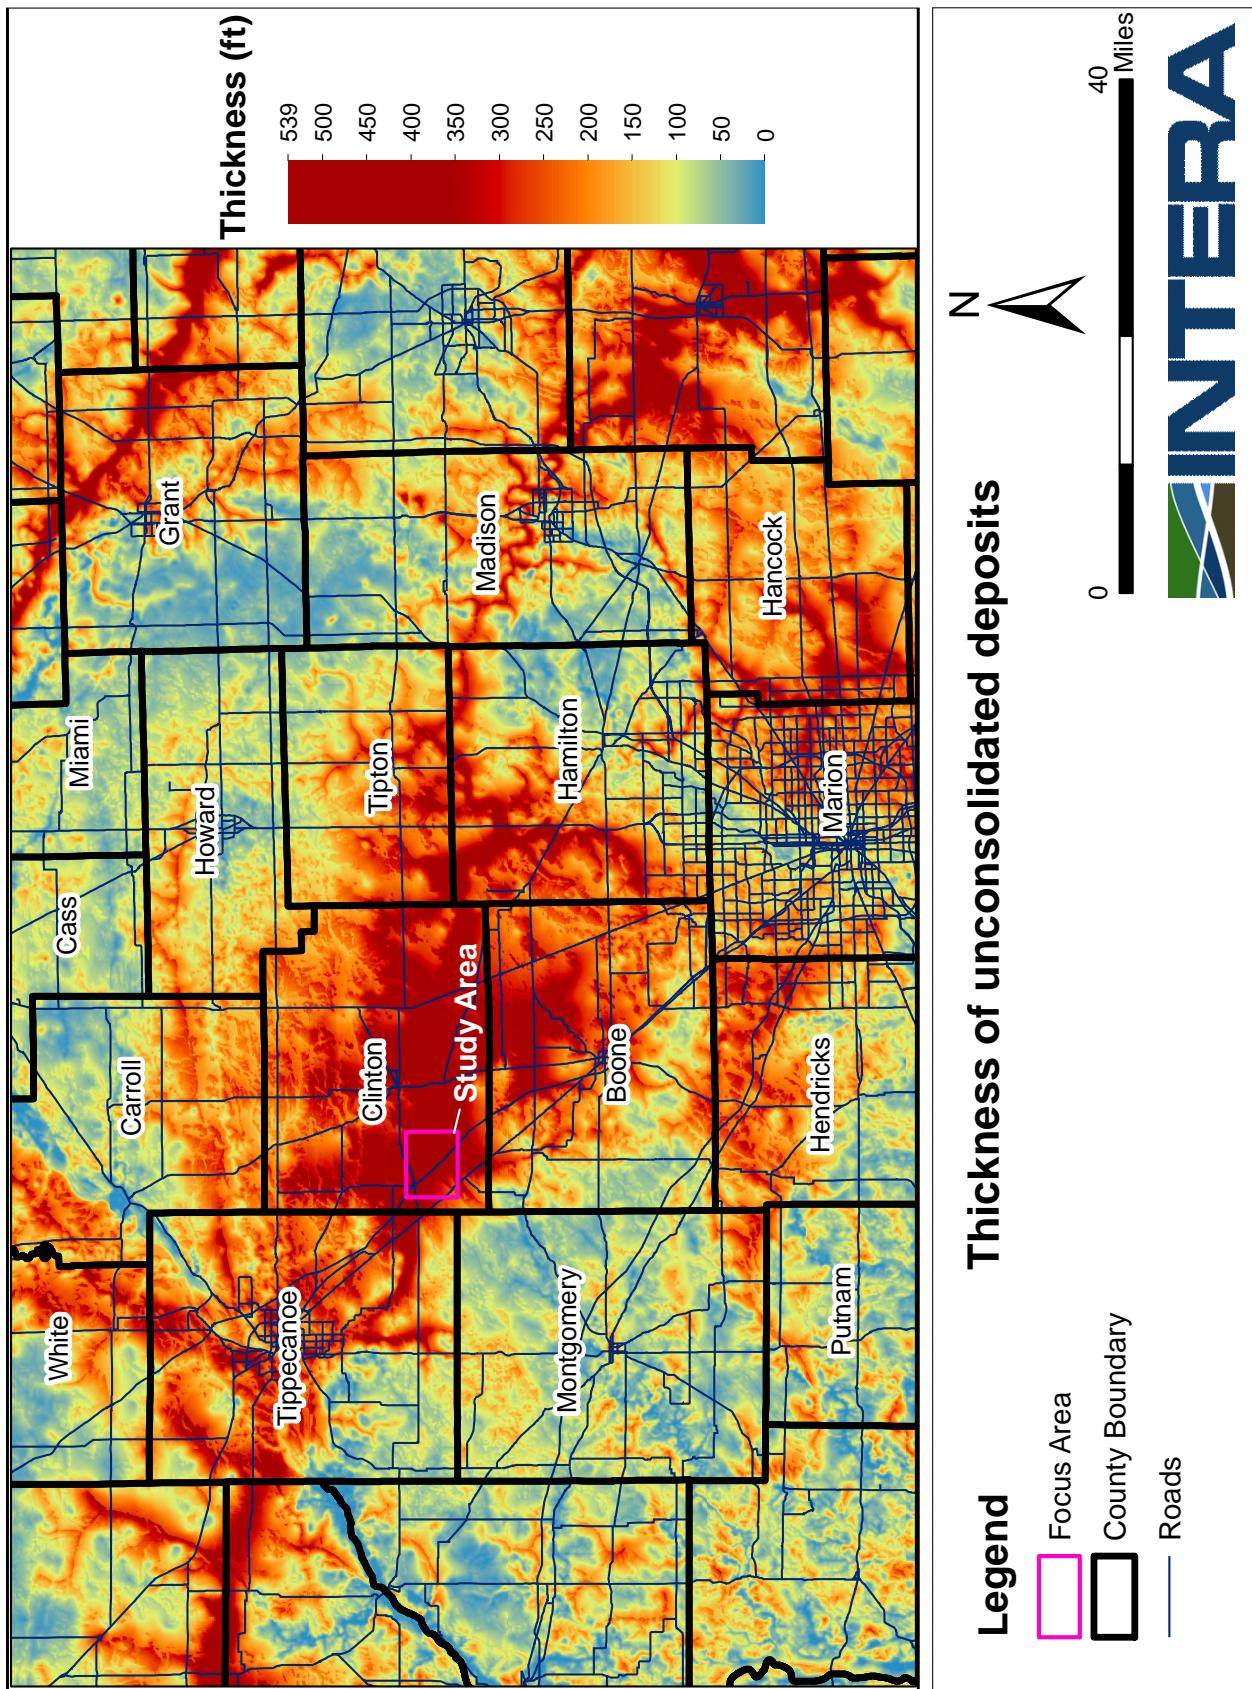

Figure 1: Thickness of the unconsolidated deposits, showing the Study Area within the Anderson Bedrock Valley.

3 Test Drilling

Access to drill sites was facilitated by written agreements with landowners, procured by a real estate team. Access was negotiated for five primary parcels on the east side of I-65, sized with the intention to locate two production wells at each while maintaining setback requirements for public supply wells (Figure 2) (A6, C1, C2, D3, J3). Access was negotiated for two smaller parcels (M1, N1) (approximately 0.5 acre each) on the west side of I-65 (secondary sites). The parcels were sized with the intention to drill a single test boring and complete as a monitoring well, if warranted. Additional access was obtained for one of the primary sites to construct test production wells and conduct hydraulic tests (J3).

All exploratory boreholes were drilled with a sonic drill rig by Cascade Drilling. Sonic drilling employs the use of high-frequency, resonant energy to advance a core barrel and casing into the subsurface. When the core barrel is retrieved from the subsurface, it produces a relatively undisturbed sample with near 100% core recovery. All borings were initially drilled with a 6 inch diameter core barrel. The recovered core samples were classified and logged according to the unified soil classification system (USCS).

3.1 Test Borings and Monitoring Wells

At each primary and secondary site, initial test borings were drilled to bedrock to characterize the entire unconsolidated section of valley fill and further define the elevation of the bedrock surface. Few existing well logs in the IDNR database extend to bedrock because sufficient yields for domestic wells are encountered within the shallow unconsolidated glacial deposits. Additional borings were drilled at the primary sites to collect soil samples for potential well design. At both primary and secondary sites, monitoring wells were constructed based on the lithology that was encountered (summarized in Table 1). The layout of test drilling activities for the primary sites is shown in Figures 3 - 4. Layouts for the two secondary sites are shown in Figure 5.

Distinct shallow and deep formations were found simultaneously at two Sites (A6, C2). The Shallow Aquifer was encountered without the Deep Aquifer at two Sites (D3, C1). The Deep Aquifer was without the Shallow Aquifer at one Site (N3). The initial borings at Site J3 encountered only the deep formation. However, subsequent borings at Site J3 to prepare for aquifer testing showed that the presence of the shallow and deep formations were highly variable across the Site.

ft = feet; bgs = below ground surface; abg = above ground surface

3.2 Test Wells

Two test production wells were constructed at Site J3 to conduct aquifer testing (Figure 2). The test wells were installed with a sonic rig by over-reaming the initial core to a borehole diameter of 12 inches. The test wells were constructed with 8 inch diameter stainless steel screen and steel casing (Table 2).

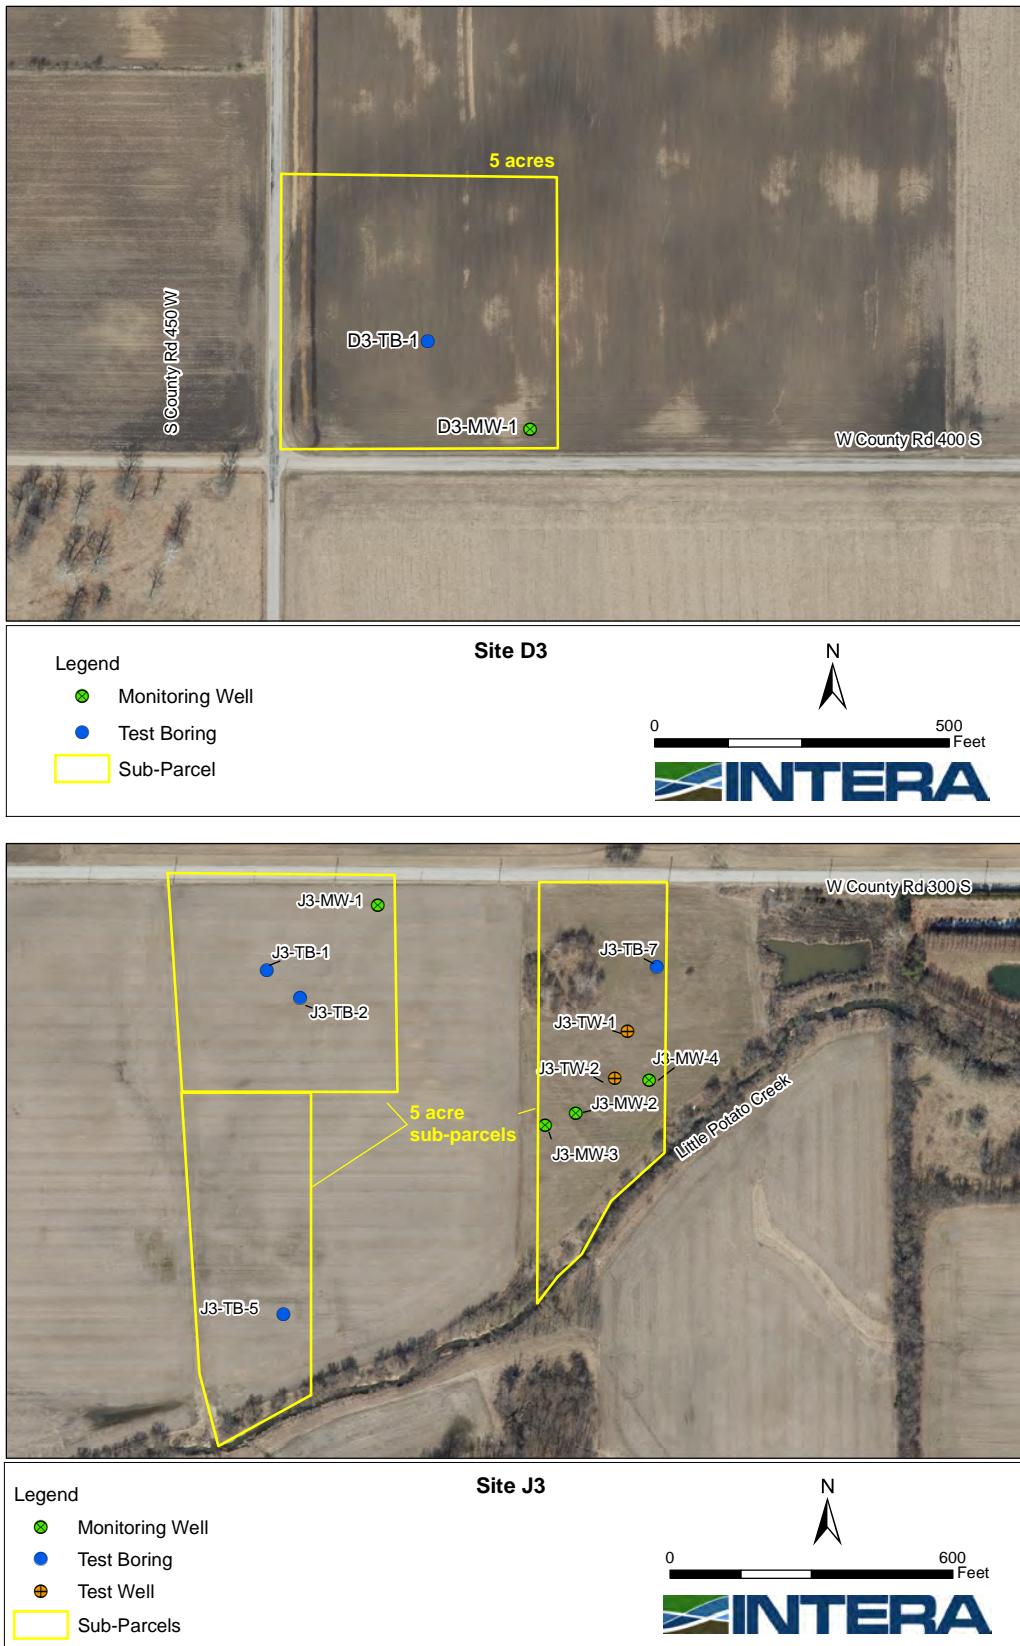

Figure 4: Layout of test drilling at Site D3 (*top*) and Site J3 (*bottom*).

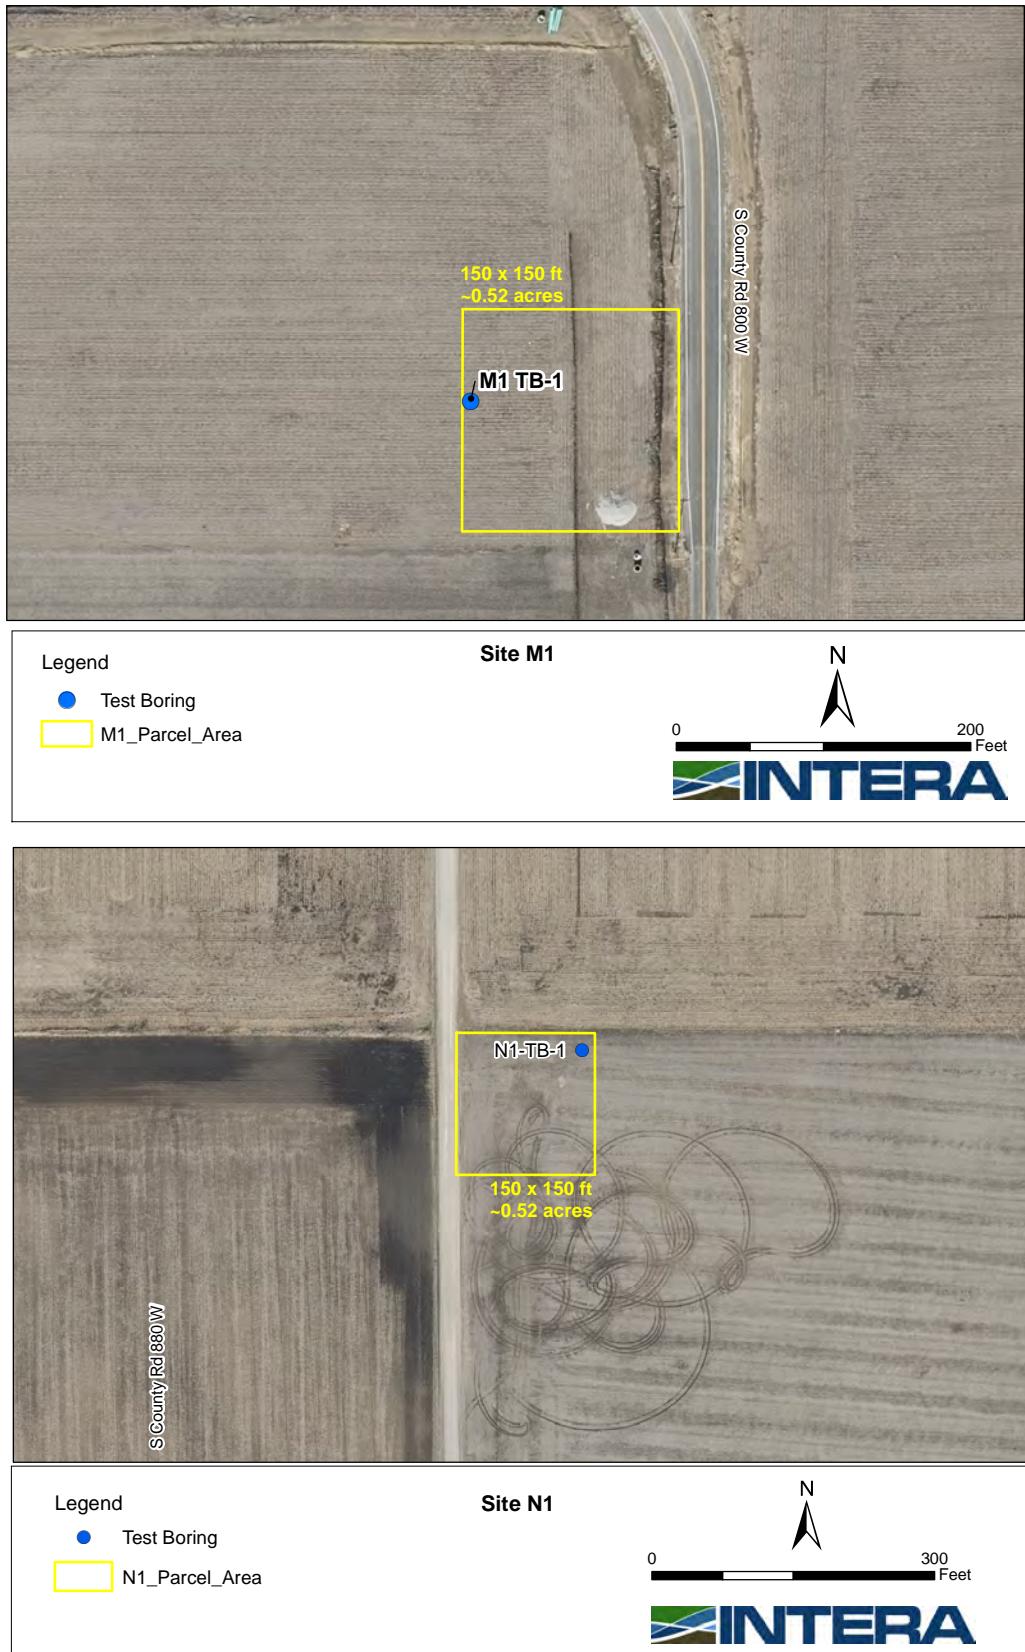

Figure 5: Layout of test drilling Site M1 (*top*) and Site N1 (*bottom*).

4 3D Geologic Model

A 3D Conceptual Geological Model (CGM) was constructed to better visualize and define the shape of the bedrock surface and unconsolidated lithology within the model domain. The model was constructed using Leapfrog Works version 2.4 software (Leapfrog). Leapfrog enables fast, detailed visualization and analysis of geologic features. This model was built using lithologic borehole data collected during drilling along with publicly available data gathered from various state and federal agencies including: the Indiana Department of Natural Resources (IDNR), the Indiana Geological Water Survey (IGWS), and the United States Geological Survey (USGS). These data sets include surficial and bedrock maps from the IGWS, a bedrock elevation model from the IGWS, a data set of well logs and associated lithologies from the IGWS iLITH database, and topography derived from digital elevation models (DEM) from the USGS.

4.1 Model Domain and Inputs

The domain of the CGM was selected to encompass drilling sites as well as the Frankfort Well Field. The extent of the domain is shown in Figure 6. The model covers 65.8 square miles in southwestern Clinton County; extending to: State Road 28 to the north, W Co Rd 700 S to the south, S Co Rd 200 E to the east, and S Co Rd 100 W to the west.

4.2 Topography

Topography in the 3D CGM was imported from USGS 1/3 arc-second DEM files (USGS, 2019). The topography represents the land surface and is also the top bounding surface for the CGM. The topography in the Study Area is mostly flat, gently sloping from northeast to the southwest. Within the study area, the elevation ranges from 892 to 806 ft amsl, with a total relief of 86 ft. An image of the entire Leapfrog model domain showing the topography is shown in Figure 7.

4.3 Bedrock Elevation

Preliminary bedrock elevation data was imported into the model from the IGWS Bedrock Topography 100-M DEM data set (Naylor, 2015). This data was refined and enhanced, particularly at each drilling site that encountered bedrock, as well as at locations of previously collected passive seismic surveys. The final bedrock topography shows the shape and extent of the bedrock surface, which lies primarily within the Anderson Bedrock Valley. Bedrock elevations range from 637 to 435 ft amsl for a total bedrock topographic relief of 202 ft (Figure 8).

Within the study area, the Anderson Bedrock Valley is a broad valley that was incised into the bedrock surface during several glacial advances and retreats since the late Pennsylvanian period (~300 million years ago). The glacial action eroded the area's bedrock and covered it with unconsolidated material through the last two hundred thousand years, when at least

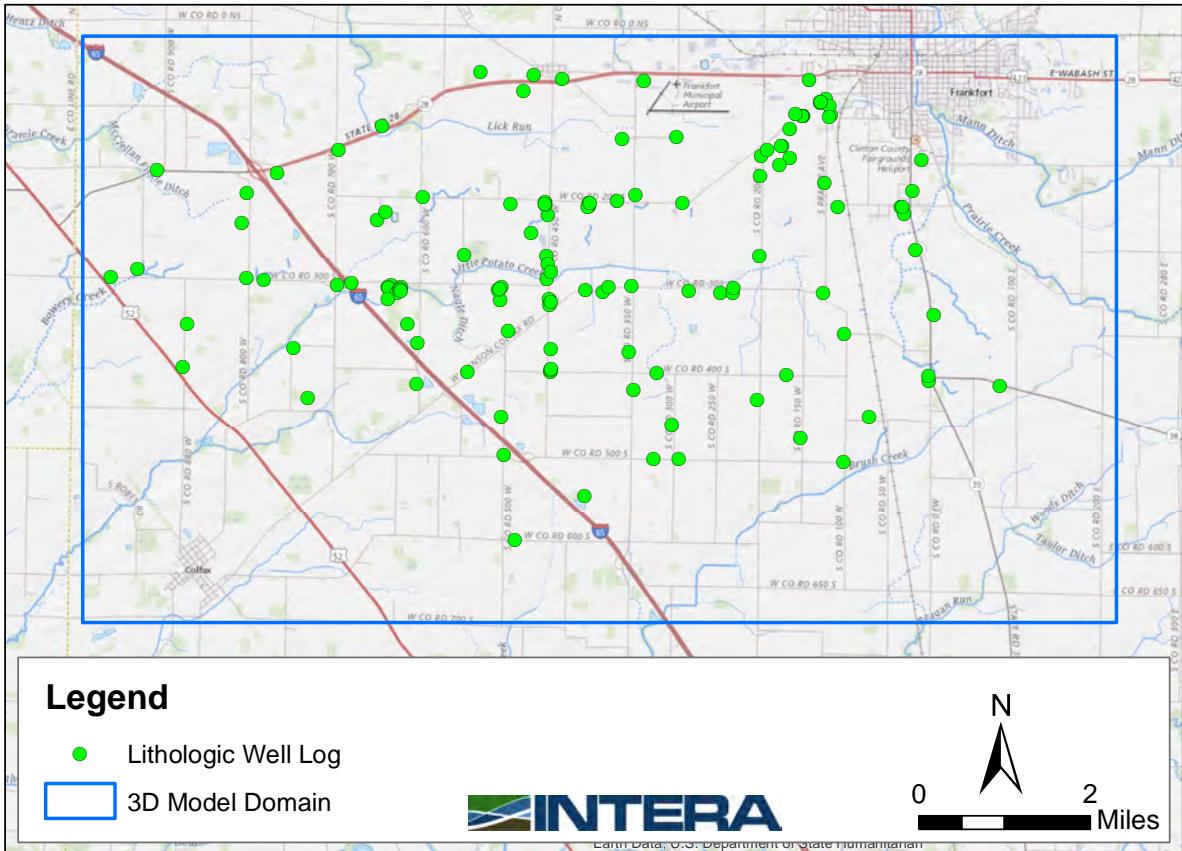

Figure 6: Model domain of the 3D geological model and well log locations.

two glacial advances and retreats (referred to as the Illinoian and the Wisconsin) crossed into the state from the north (Gray, 2000). The current bedrock surface is more elevated in the northeastern side of the county, then dips into a valley system in the southwest. The Anderson Bedrock Valley traverses through the southern side of the county. This valley was a major drainageway for the massive amount of glacial meltwater produced by the retreat of the Illinoian and Wisconsin events. The Anderson valley has since filled with unconsolidated clay and silt-rich till interbedded with sand and gravel deposits ranging in thickness from 425 to 179 ft within the study area.

4.4 Well Logs

Along with lithologic data from the 22 new sonic boreholes drilled within the study area, 103 well logs were added to the CGM from the IDNR water well database. Only boreholes with verifiable locations were used in the model. Final locations of well logs are shown in Figure 6. All of the borings, including well logs from the IDNR are listed in Appendix B. Lithologic data from each log was grouped into three main categories based on their aquifer characteristics: Clay/Silt, Sand/Gravel, and Bedrock. Fine-grained materials such as clay, silt, or till were

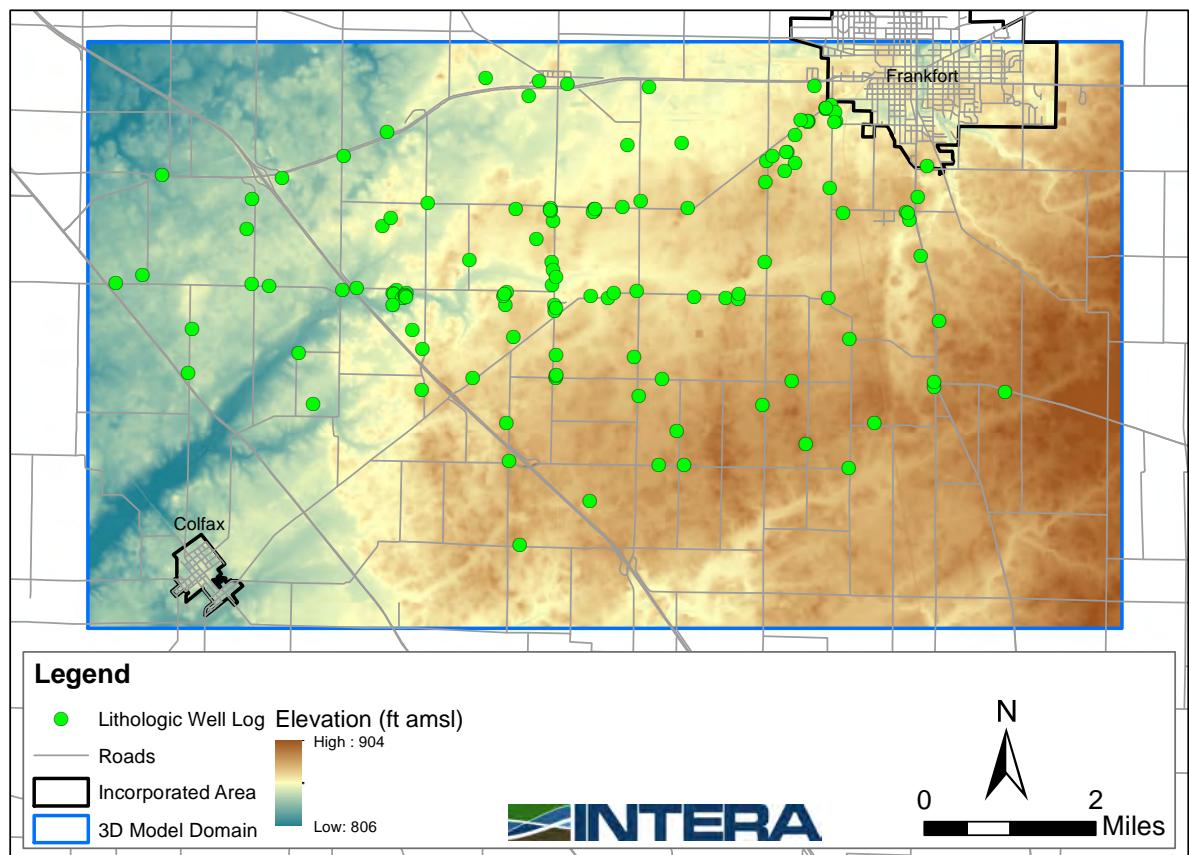

Figure 7: Topography within the 3D geologic model domain.

grouped into the Clay category, coarse grained material such as sand, gravel, or cobbles were grouped into the Sand and Gravel category, and hard bedrock material were grouped into the Bedrock category.

4.5 Model Development

The 3D CGM was in large part developed to delineate in detail the size, extent, and geometry of various lithologic layers throughout the Study Area that greatly affect how water moves through the system. Geologic formations were subdivided to illustrate hydrologic properties. The lithologic information was subdivided into two main categories, bedrock and unconsolidated. The bedrock category covers lithified rock material located at depth below the unconsolidated materials. For this model, the bedrock is subdivided into units based on previous mapping. The bedrock units within this model include: the Borden Group, the New Albany Shale, the Muscatatuck formation, and the Bainbridge formation. The unconsolidated category includes all material that is on top of the bedrock. These are mainly loose sediment deposits such as clays, silts, sands, gravels, and boulders. These unconsolidated materials were grouped into two main categories based on permeability. The more permeable layers of sand and gravel were grouped together, and less permeable layers of clay and silt were grouped together. The resulting model illustrates sand/gravel as blue and clay/silt as yellow as shown in Figure 9.

4.6 Geologic Cross-Sections

Ten geologic cross-sections were created using the 3D CGM to illustrate variations in the generalized lithologies across the study area. Five cross-sections were drawn west-to-east (A-A', B-B', C-C', D-D', and E-E') and five north-to-south (F-F', G-G', H-H', I-I', and J-J'). The location of each cross-section is shown in Figure 10. The cross-sections are shown as Figures 11-20.

4.7 Discussion

This model defines four discontinuous layers of sand and gravel, separated by thick layers of silt and clay. The model shows the bottom sand and gravel layer (Deep Aquifer) as regionally continuous and thicker in most sections than the sand and gravel layers above. The model also shows the upper most sand and gravel layer (Shallow Aquifer) as relatively continuous throughout the study area, but generally thinner than the Deep Aquifer. The model also illustrates two discontinuous layers of sand and gravel between the Shallow and Deep Aquifers. These middle layers are shown with higher variability, showing relatively thick sections in some areas that pinch out in other areas. In general, the model shows the high local variability in extent and geometry of unconsolidated deposits, at the same time as the regionally continuous nature of the Shallow and Deep aquifers.

5 Hydraulic Testing

In September 2022, two extended aquifer pumping tests were conducted at Site J-3 utilizing Test Wells TW-1 and TW-2. The objective of the aquifer pumping tests was to characterize the hydraulic properties of the unconsolidated aquifer. Tables 1 and 2 summarize the well construction details of TW-1 and TW-2 and the monitoring well network. TW-1 was constructed in the deeper zone of the unconsolidated aquifer (screen interval 212 to 232 feet bgs), and TW-2 was screened in the upper zone (screen interval 107 to 137 feet bgs). TW-2 was pumped at an average pumping rate of approximately 391 gpm for seventy-two hours from September 9th to September 12th, 2022. TW-1 was pumped at an average pumping rate of approximately 76 gpm for 72 hours from September 19th to 22nd, 2022.

For each aquifer pumping test, the pump discharge rate was measured with an inline digital flowmeter. Water was pumped through flexible hose and then discharged onto plastic sheeting and silt fencing to minimize erosion, which eventually flowed into Little Potato Creek south of TW-1 and TW-2 (Figure 21). During each aquifer test (including drawdown and recovery periods), water levels were measured and recorded in the pumping well and monitoring well network with In-Situ Inc. brand down-hole pressure transducers and digital data loggers. Site cross sections are presented in Figures 22 - 25.

5.1 Results

The drawdown and recovery data from the TW-1 aquifer test are shown as a hydrograph in Figure 26. The TW-1 aquifer test hydrographs illustrate that TW-1 experienced over 145 feet of drawdown (at an average pumping rate of 76 gpm) during the course of the test, whereas monitoring wells MW-1, MW-3, and MW-4 experienced less than 1 foot of drawdown. Although TW-1 was hydraulically developed after construction with airlifting and dual surge blocks, the extensive drawdown suggests that the well either had a very low efficiency or the aquifer in the direct vicinity had a low transmissivity value. The drawdown data for MW-1, MW-3, and MW-4 was highly erratic likely due to fluctuations in the TW-1 pumping rate. Overall, the data collected from the TW-1 aquifer test did not have sufficient resolution to calculate aquifer hydraulic parameters using analytic aquifer curve matching techniques.

TW-1, MW-1, MW-3, and MW-4 were also monitored during the TW-2 aquifer test, and the data were analyzed to estimate aquifer hydraulic parameters. The drawdown and recovery data from the TW-2 aquifer test are shown as a hydrograph in Figure 27. Overall, the data from the TW-2 aquifer test is higher quality as compared to the TW-1 data and is suitable for calculating aquifer hydraulic parameters using analytical type curve matching techniques. After seventy-two hours of continuously pumping at approximately 391 gpm, TW-2 experienced approximately 22 feet of drawdown, which equates to a final specific capacity of 18 gpm/ft. The relatively high specific capacity value suggests that the aquifer in the vicinity of TW-2 has a relatively high transmissivity value.

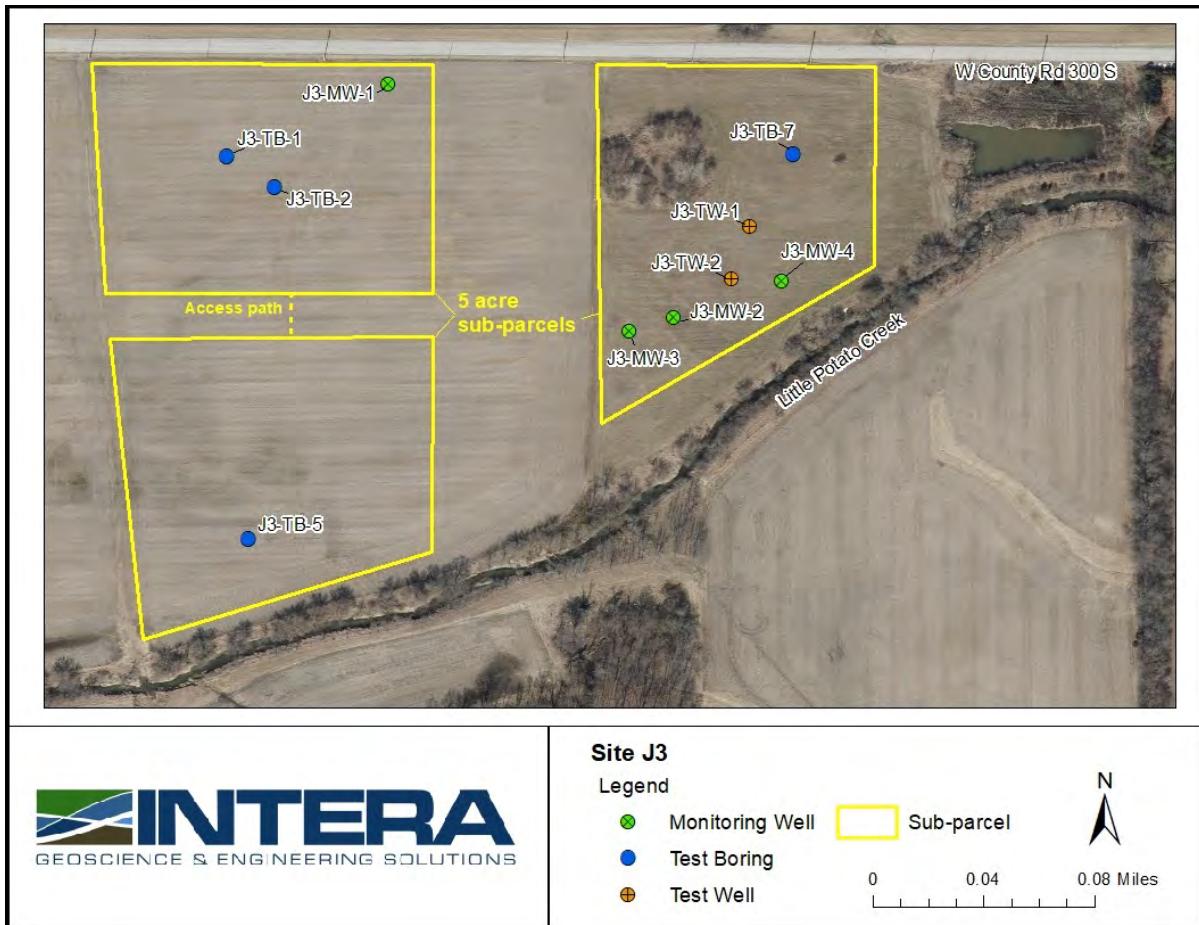

Figure 21: Test well and monitoring well locations at Site J3.

Figure 22: Map of geologic sections through Site J3.

5.2 Analysis

The drawdown and recovery data from TW-2 and the monitoring well network were analyzed with AQTESOLV for Windows Aquifer Analysis Program version 4.5 (Hydrosolve Inc., 1996-2007) to provide estimates of the hydraulic properties of the unconsolidated aquifer. The Hantush semi-confined/leaky aquifer analytical technique (Hantush, 1960) was used to calculate the hydraulic parameters for all of the wells monitored during the TW-2 aquifer test. Partial penetration was incorporated into the analysis to account for the different well screen intervals and depths of the test wells and monitoring wells (Tables 1 and 2). The Hantush semi-confined/leaky aquifer solution is consistent with the conceptual geologic model of the study area which illustrates the presence of an upper low permeability confining layer overlying the permeable sand and gravel formation. The results of the analysis are included in Figures 28 through 31.

The calculated aquifer hydraulic parameters from TW-2 aquifer test are summarized in Table 3. There is a wide range in calculated hydraulic parameters from the TW-2 aquifer test. The range in calculated aquifer hydraulic parameters is likely related to the large lateral and vertical variation in lithology encountered in the test borings, which is consistent with the depositional environment associated with buried bedrock valley aquifers. Note that the aquifer hydraulic parameters calculated from analyzing TW-1, MW-1, MW-3, MW-4 and A6-MW-1D simultaneously likely provide a good average approximation of the overall unconsolidated

6 Water Quality

INTERA collected raw-water samples from select monitoring wells and the two test wells to characterize the water-quality characteristics of the aquifer system. The monitoring well samples were collected over the course of four days between 8/1/22 and 8/4/22 and the test well samples were collected during the respective aquifer tests (Section 5). The samples were analyzed for inorganic and metal constituents by Eurofins Laboratory, Inc.

The analytical lab results are summarized in three tables: Table 4 presents field parameters and the results for general chemistry from the monitoring wells, Table 5 shows the results for 29 metal constituents for the monitoring wells, and Table 6 presents the results from the test wells. Full lab reports are included as Appendix C.

Figure 32 shows a piper plot with results from the monitoring wells. A piper plot is a tri-linear diagram which summarizes and illustrates the major inorganic species in the sample. A piper diagram can be used to compare different water samples and determine water type. The clustering of data points on the plot indicates that the sources are similar in type. All of the water sampled can be classified as calcium-bicarbonate water, which is typical for Indiana.

All of the samples exhibit elevated iron and manganese concentrations, with iron ranging from 0.62 to 3.1 mg/L and manganese ranging from 0.07 to 1.3 mg/L (Tables 5 and 6). All of the samples exceeded the USEPA secondary maximum contaminant level (SMCL) of 0.3 mg/L for iron and 0.05 mg/L for manganese. For both iron and manganese, the SMCL is set to minimize corrosion, staining, and undesirable taste and odor effects. Given the observed concentrations, treatment would be required for both iron and manganese. Most iron and manganese removal treatment processes incorporate oxidation to convert dissolved forms of the metals to a solid, followed by a filtration process.

Results from Site J3 suggest that arsenic levels are elevated at some locations in the aquifer system above the drinking-water standard. Elevated arsenic concentrations in groundwater sources are a national and regional concern (Warner et al., 2003). One of the monitoring wells, J3-MW-2D, and both test wells exhibited arsenic concentrations well above the USEPA maximum contaminant level (MCL) of 0.010 mg/L (Tables 5 and 6). The arsenic MCL is in place to minimize potential health effects from long-term exposure, including skin damage, problems with circulatory systems, and increased cancer risk. Arsenic is naturally occurring in groundwater, entering water sources through erosion of natural deposits in rocks. The mobilization of arsenic in groundwater can occur if there is a source of arsenic in the geologic materials and if the geochemical conditions are conducive to transport. Arsenic concentrations higher than the MCL would require treatment. Given the specific observed concentrations higher than the MCL and the general range of observed iron concentrations, there is the potential to promote the removal of arsenic with iron removal processes for drinking water via adsorption and co-precipitation.

7 Groundwater Accessibility Model

Exploratory borings and soil descriptions at individual testing sites indicate that there is significant spatial variability in thicknesses, depths, and material descriptions of permeable layers throughout the study area. Further, hydraulic testing of Site J3 indicates that aquifer hydraulic properties vary spatially across the site. Site J3 is different than the Frankfort Municipal Well Field as the Shallow and Deep aquifers are less hydraulically separated and the soil material varies from silt through medium sand, rather than the coarser materials encountered at the Frankfort Well Field. Results from the aquifer testing and data analysis at J3 provide no definitive conceptual model of recharge to the aquifers that supports a conclusive estimate of sustainable yield. However, we use conservative assumptions and engineering experience analyzing well fields in similar settings to estimate the sustainable yield of the J3 Site.

7.1 Hydrogeologic Conceptual Model and Parameterization

A hydrogeologic conceptual model was developed from boring logs at sites J3 and A6, the 3D geologic model, and the results of hydraulic testing of J3-TW-2. The conceptual model was implemented in the transient groundwater flow modeling code TTim to evaluate the potential yield of the site (Bakker, 2013b,a). The conceptual model is illustrated in Figure 33. The model consists of a fixed water level overlying the site; the regional water table is controlled by the many drain tiles and surface drainages that have been constructed in the farm fields to control groundwater flooding of crops. The source of water supplying the sustainable yield at the site is assumed to be vertical leakage from the the water table which is replenished by recharge from precipitation and infiltration at the land surface, as illustrated in Figure 33.

The hydraulic properties associated with the layering illustrated in Figure 33 are summarized in Table 7. The uppermost model layer represents a till layer and is simulated as a leaky layer (Leaky Layer 0). A fixed water table overlies the layer.

Aquifer Layer 1 represents another thick layer of clay encountered in site borings, but is represented as an aquifer layer rather than a leaky layer. Leaky Layer 1 and Leaky Layer 2 sandwich Aquifer Layer 1 from the top and bottom, and approximate the vertical resistance to flow of Aquifer Layer 1 in the numerical model. The combined resistances of Leaky Layers 1, 2, and 3 are based on the leakance evaluated from the pumping test analysis of 1,200 days (Table 3). A calibrated value of 3,200 days was estimated by simulation of the aquifer test, as described below in Section 7.2.

$$c_1 + c_2 + c_3 = 3,200 \text{ days}$$

The individual resistances were initially specified according to the relative thickness of Leaky Layer 0 (30 feet) and Aquifer Layer 0 (40 feet)

$$c_1 = \frac{30}{70} \times 3,200 = 1,400 \text{ days}$$

Table 7: Properties of the aquifer layers (*top*) and the leaky layers (*bottom*) specified in the groundwater yield model.

Aquifer Layer	Thickness, H (ft)	Hydraulic Conductivity, k (ft/day)	Specific Storage, S_s (1/ft)
0	20	55	1.5×10^{-5}
1	39	.01	0
2	34	55	1.5×10^{-5}
3	34	55	1.5×10^{-5}
4	34	55	1.5×10^{-5}
5	34	55	1.5×10^{-5}

Notes: ft = feet. ft/day = feet per day.

Leaky Layer	Thickness, H^* (ft)	Resistance, c (day)	Specific Storage, S_s (1/ft)
0	30	1200	0
1	1	1000	0
2	1	1000	0
3	1	3	0
4	1	3	0
5	1	3	0

Notes: ft = feet.

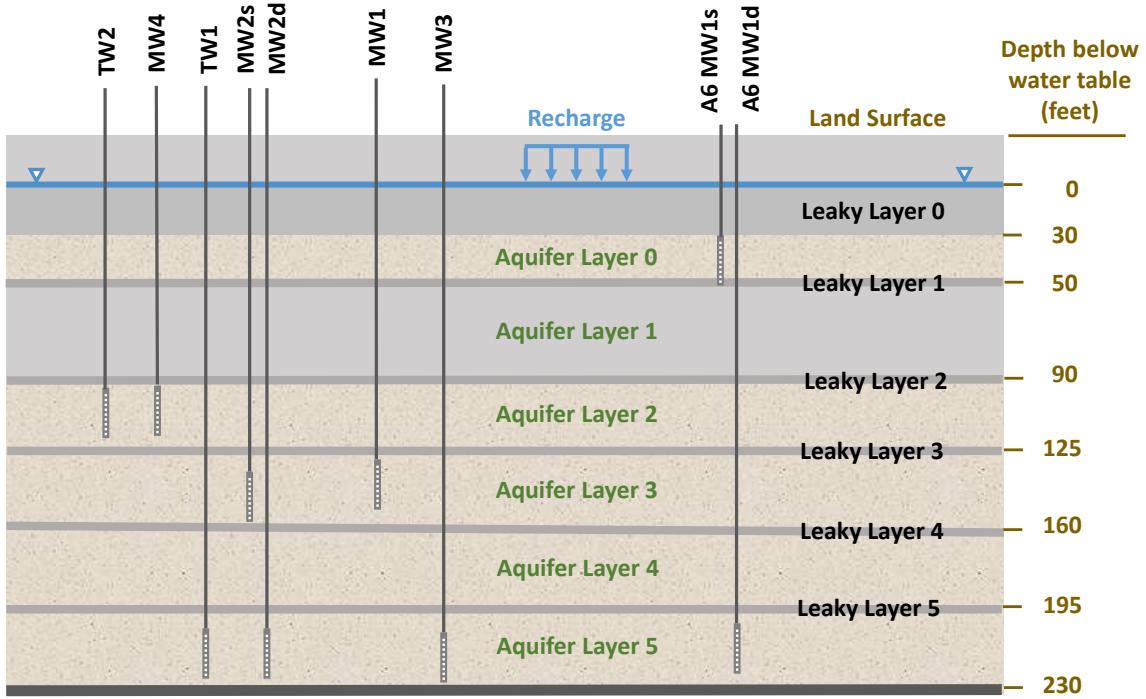

Figure 33: Implementation of the hydrogeologic conceptual model.

$$c_2 + c_3 = \frac{40}{70} \times 3,200 = 1,800 \text{ days}$$

Final values of 1,200 days for Leaky Layer 0 and 2,000 days for Leaky Layer 1 and 2 combined (Table 7) were adjusted from the initial values based on the aquifer test simulation described below.

The transmissivity of the combined permeable aquifer layers (Aquifer Layers 0, 2, 3, 4, and 5) is based on results of the pumping test analysis (Table 3), and adjusted during the aquifer test simulation:

$$T = (4 \text{ layers} \times 34 \text{ feet}/\text{layer} + 20 \text{ feet}) \times 55 \text{ feet/day} = 8,600 \text{ ft}^2/\text{day}$$

The Specific Storage of Aquifer Layers 0, 2, 3, 4, and 5, are based on the pumping test analysis. The specific storage of Aquifer Layer 1 is specified as zero, while the remaining Leaky Layers have values of $1.5 \times 10^{-5} \text{ days}^{-1}$. Leaky Layers 3, 4, and 5 are used to simulate vertical anisotropy ratio of 0.2 in Aquifer Layers 2 through 5; the resistance of each leaky layer is based on the vertical hydraulic conductivity of half the overlying and underlying aquifer layer,

$$c_i = \frac{0.5H_{i-1}}{0.2k_{i-1}} + \frac{0.5H_i}{0.2k_i} = \frac{34 \text{ ft}}{0.2 \times 55 \text{ ft/day}} = 3 \text{ days}$$

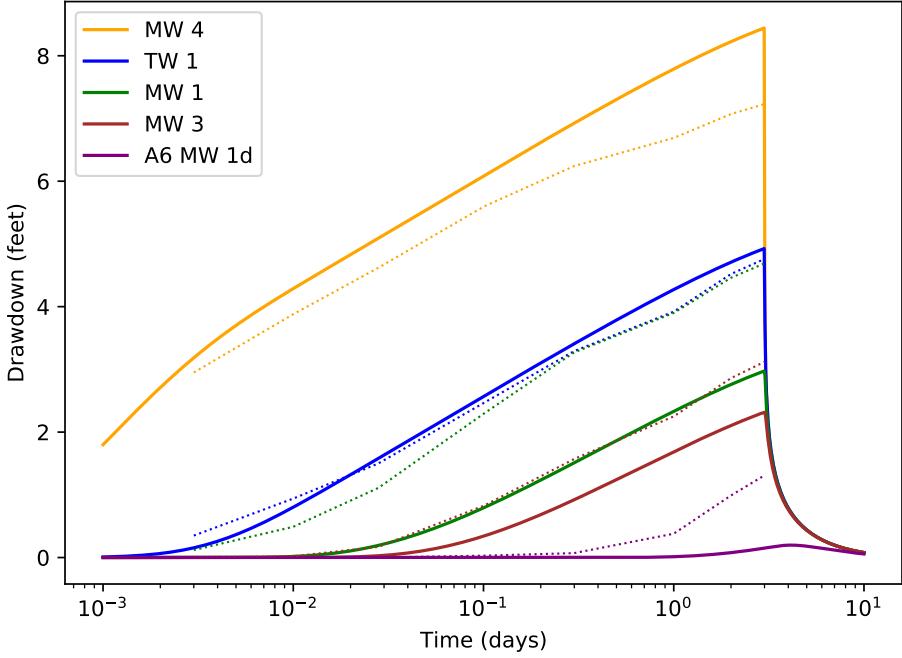

Figure 34: A comparison of simulated and observed drawdown in the monitoring well network at Site J3. Simulated results are solid lines, while observations are dotted lines.

This anisotropy ratio was evaluated from the pumping test analysis (Table 7).

7.2 Aquifer Test Simulation

The numerical model described above allows for a more general description of the aquifer than allowed for in the AQTESOLV software used to estimate aquifer parameters. While the parameters specified in the numerical model are based on the AQTESOLV results, the more general parameterization of the numerical model was assessed by simulating the aquifer test conducted at J3 by pumping TW-2 for 72 hours. Figure 34 presents a comparison of simulated drawdown and observed drawdown in the network of monitoring wells. The results are comparable to the AQTESOLV results, with an improved response at MW-3.

7.3 Evaluation of Potential Yield

The model was used to estimate the potential sustainable yield of the a hypothetical well field constructed at the J3 Site. The physical properties of the simulated production wells were assumed to be similar to test well J3-TW-2 (see Table 8). The potential yield of the site was simulated by specifying an instantaneous drop in water level at the well to 90 feet below the water table. As illustrated in Figure 33, this drops the water level in Aquifer Layer 2 to the

Table 8: Assumed production well properties.

Property	Symbol	Units	Value
Effective radius	r_w	ft	0.5
Screen length	L	ft	34
Efficiency	ϵ	%	60
Max drawdown	D	ft	90

Note: ft = feet.

Table 9: Potential yield of a well field near Site J3.

Number of wells	Well Spacing (ft)	Total Yield		Total Yield	
		100% Efficiency (gpm)	(MGD)	60% Efficiency (gpm)	(MGD)
1	–	890	1.3	540	0.8
3	100	1980	2.8	1190	1.7
3	500	2280	3.3	1370	2.0
3	1000	2390	3.4	1430	2.1
3	5000	2620	3.8	1570	2.3

Notes: ft = feet. gpm = gallons per minute. MGD = million gallons per day.

top of the layer. The simulated wells are screened over the full depth of Aquifer Layer 2. The discharge of the well is then simulated through time. Results are illustrated in Figure 35, for a single well, three wells with a spacing of 100 feet, and 3 wells with a spacing of 1,000 feet. In all cases, a steady-state discharge is obtained after about 12 days of pumping. For a single well, the steady, or sustainable yield, is 894 gpm when operating at 100% efficiency.

Figure 36 illustrates a section through the well fields with resulting water levels in each aquifer layer for each of the three scenarios, after a steady-state condition has been reached.

The potential sustainable yields at Site J3, for a single well and several 3-well configurations with differing spacing are presented in Table 9. Wells constructed with 100% efficiency at this site would be unlikely due to the variation in the physical description of aquifer material noted on the boring and well construction logs. A practical well efficiency of 60% is assumed for each of the simulated wells, based on engineering experience. The predicted well field yields are presented in the final two columns of Table 9, with values in bold lettering.

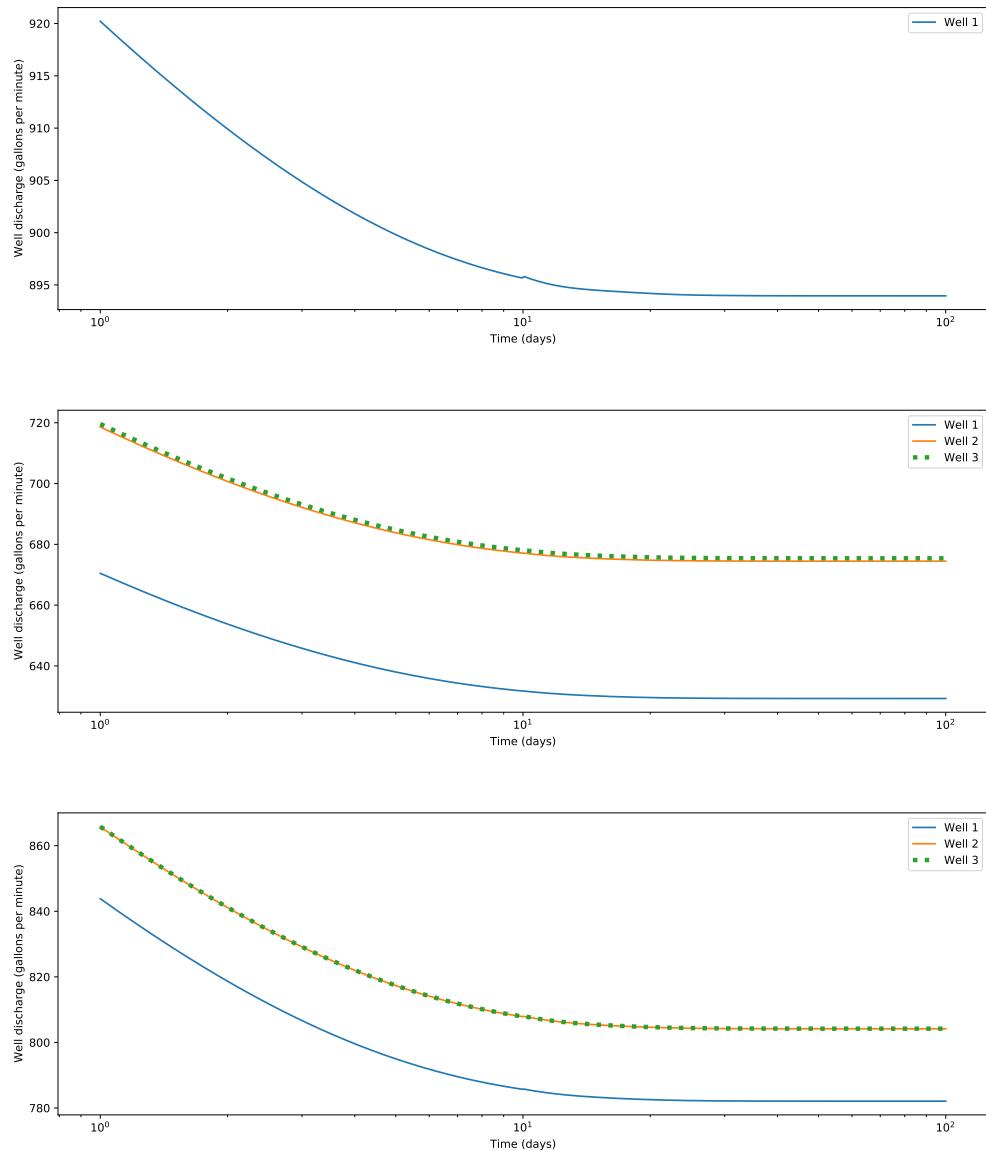

Figure 35: Potential yield for well field with a maximum drawdown of 90 feet and 100% efficiency; (top) single well, (middle) three wells at 100 foot spacing, and (bottom) 1000 foot spacing. All wells operating at 100 % efficiency.

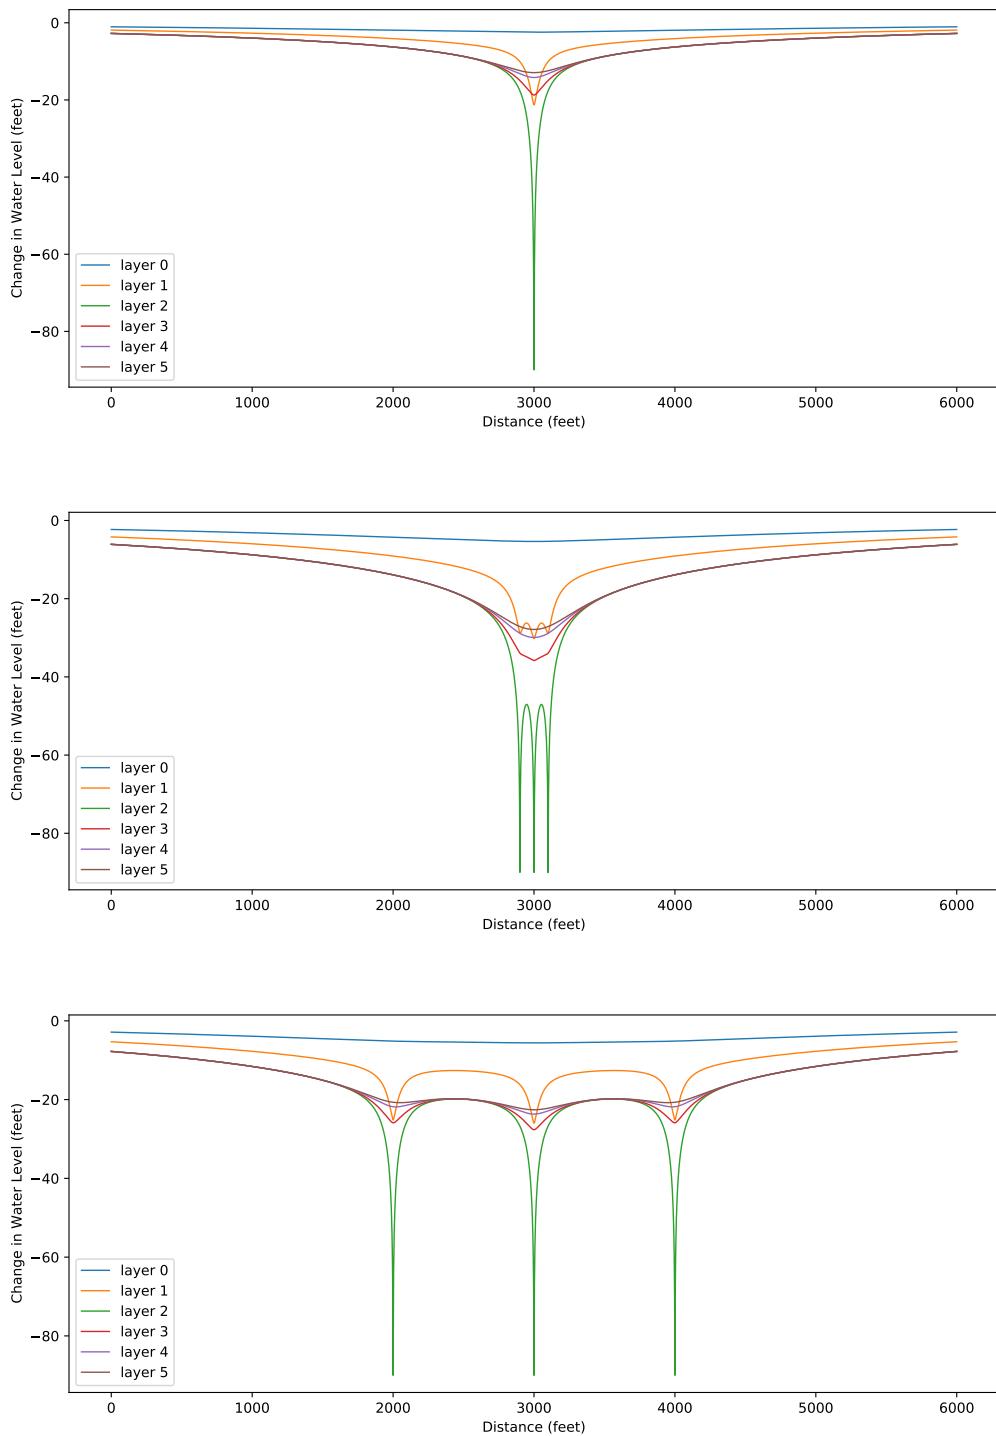

Figure 36: Water levels at steady state for (*top*) a single well, (*middle*) three wells with 100 foot spacing, and (*bottom*) 1,000 foot spacing. The wells are screened in Aquifer Layer 2.

7.4 Conclusions

The source of long-term, sustainable yield to a well field located at site J3 is assumed to be from leakage from the shallow clay and sand aquifer, and is therefore highly dependent on the characteristics of the clay layers, specifically the resistance to vertical flow. During the three day pumping test, a semiconfined response was observed in the nearest monitoring well, J3-MW-4, but it was less evident in the remaining monitoring wells. It is likely that other factors, typical of this glacial till environment, affect recharge to the deep aquifer layers. These features may include high-permeability channels, spatially variable hydraulic properties, and discontinuous clay lenses, which cannot be directly assessed by a pumping test. Here we use the results of the aquifer test analysis along with engineering judgment based on experience designing well fields in similar settings to estimate the sustainable yield of a well field constructed at Site J3.

Well field scenarios with three wells were tested, based on the size of the parcel. We expect a maximum yield of 2.1 MGD at the J3 Site with a well spacing of 1,000 feet. The A6 Site lies approximately a mile away from Site J3. Exploratory borings suggest that Site A6 may be more productive than the J3 Site, although it was not tested in this study. Geologic and hydrologic conditions in the region are highly spatially variable and further aquifer testing would be required to estimate yields for other sites. An additional well field constructed at the A6 Site would not be expected to significantly affect the yield of the J3 Site due to the separation distance. A conservative estimate of the total yield of two well fields, each consisting of three wells, constructed at Site J3 and Site A6 is 4 MGD.

The test results in this report meet all 2003 NELAC, 2009 TNI, and 2016 TNI requirements for accredited parameters, exceptions are noted in this report. This report may not be reproduced except in full, and with written approval from the laboratory. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

This report has been electronically signed and authorized by the signatory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

Results relate only to the items tested and the sample(s) as received by the laboratory.

Comments

No additional comments.

Receipt

The samples were received on 8/8/2022 1:50 PM. Unless otherwise noted below, the samples arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 1.2° C.

Receipt Exceptions

The following sample(s) was received with less than 2 days remaining on the holding time or less than one shift (8 hours) remaining on a test with a holding time of 48 hours or less. As such, the laboratory had insufficient time remaining to perform the analysis within holding time: C1-MW-1 (500-220535-1), C2-MW-1S (500-220535-2), C2-MW-1D (500-220535-3), J3-MW-2S (500-220535-4), J3-MW-2D (500-220535-5), D3-MW-1 (500-220535-6), A6-MW-1S (500-220535-7) and A6-MW-1D (500-220535-8).

Metals

No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

General Chemistry

Method 9056A: The following samples was received outside of holding time for analytes Nitrate as N, Nitrite as N and Orthophosphate as P: C1-MW-1 (500-220535-1), C2-MW-1S (500-220535-2), C2-MW-1D (500-220535-3), J3-MW-2S (500-220535-4), J3-MW-2D (500-220535-5), D3-MW-1 (500-220535-6), A6-MW-1S (500-220535-7) and A6-MW-1D (500-220535-8).

Method 9056A: The closing continuing calibration verification (CCV) associated with batch 500-669146 recovered 2% below the lower control limit for Orthophosphate as P. Only the batch QC samples (500-220535-A-3 MS) and (500-220535-A-3 MSD) were associated with this CCV ; therefore, the data have been reported.

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Qualifiers

Metals

Qualifier	Qualifier Description
4	MS, MSD: The analyte present in the original sample is greater than 4 times the matrix spike concentration; therefore, control limits are not applicable.
F5	Duplicate RPD exceeds limit, and one or both sample results are less than 5 times RL, and the absolute difference between results is < the upper reporting limits for both.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

General Chemistry

Qualifiers

Qualifier	Qualifier Description
^	Continuing Calibration Verification (CCV) is outside acceptance limits, low biased.
F1	MS and/or MSD recovery exceeds control limits.
H3	Sample was received and analyzed past holding time.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation

Abbreviation	These commonly used abbreviations may or may not be present in this report.
□	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Login Number: 220535

List Source: Eurofins Chicago

List Number: 1

Creator: Buckley, Paula M

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	
The cooler's custody seal, if present, is intact.	True	
Sample custody seals, if present, are intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	1.2
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the containers received and the COC.	True	
Samples are received within Holding Time (excluding tests with immediate HTs)	False	Refer to Job Narrative for details.
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	N/A	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

The test results in this report meet all 2003 NELAC, 2009 TNI, and 2016 TNI requirements for accredited parameters, exceptions are noted in this report. This report may not be reproduced except in full, and with written approval from the laboratory. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

This report has been electronically signed and authorized by the signatory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

Results relate only to the items tested and the sample(s) as received by the laboratory.

Comments

No additional comments.

Receipt

The sample was received on 9/12/2022 3:40 PM. Unless otherwise noted below, the sample arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 3.0° C.

Metals

No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

General Chemistry

No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

Definitions/Glossary

Client: INTERA Inc

Job ID: 500-222084-1

Project/Site: Clinton County Test Production Wells

Qualifiers

Metals

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
¤	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	
The cooler's custody seal, if present, is intact.	True	
Sample custody seals, if present, are intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	
Cooler Temperature is recorded.	True	3.0
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the containers received and the COC.	True	
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	N/A	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A

The test results in this report meet all 2003 NELAC, 2009 TNI, and 2016 TNI requirements for accredited parameters, exceptions are noted in this report. This report may not be reproduced except in full, and with written approval from the laboratory. For questions please contact the Project Manager at the e-mail address or telephone number listed on this page.

This report has been electronically signed and authorized by the signatory. Electronic signature is intended to be the legally binding equivalent of a traditionally handwritten signature.

Results relate only to the items tested and the sample(s) as received by the laboratory.

Comments

No additional comments.

Receipt

The sample was received on 9/15/2022 2:57 PM. Unless otherwise noted below, the sample arrived in good condition, and where required, properly preserved and on ice. The temperature of the cooler at receipt was 10.1° C.

Metals

No analytical or quality issues were noted, other than those described in the Definitions/Glossary page.

General Chemistry

Method 300.0: The laboratory control sample (LCS) and / or laboratory control sample duplicate (LCSD) for analytical batch 500-674869 recovered outside control limits for the following analytes: Nitrite as N and Orthophosphate as P. These analytes were biased high in the LCS and were not detected and short hold in nature in the associated samples; therefore, the data have been reported.

Method 300.0: The continuing calibration verification (CCV) associated with batch 500-674869 recovered above the upper control limit for Orthophosphate as P. The samples associated with this CCV were QC for the affected analytes; therefore, the data have been reported. The associated sample is impacted: (CCV 500-674869/13).

No additional analytical or quality issues were noted, other than those described above or in the Definitions/Glossary page.

Definitions/Glossary

Client: INTERA Inc

Job ID: 500-222317-1

Project/Site: Clinton County Test Production Wells

Qualifiers

Metals

Qualifier	Qualifier Description
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

General Chemistry

Qualifier	Qualifier Description
*+	LCS and/or LCSD is outside acceptance limits, high biased.
^+	Continuing Calibration Verification (CCV) is outside acceptance limits, high biased.
J	Result is less than the RL but greater than or equal to the MDL and the concentration is an approximate value.

Glossary

Abbreviation	These commonly used abbreviations may or may not be present in this report.
□	Listed under the "D" column to designate that the result is reported on a dry weight basis
%R	Percent Recovery
CFL	Contains Free Liquid
CFU	Colony Forming Unit
CNF	Contains No Free Liquid
DER	Duplicate Error Ratio (normalized absolute difference)
Dil Fac	Dilution Factor
DL	Detection Limit (DoD/DOE)
DL, RA, RE, IN	Indicates a Dilution, Re-analysis, Re-extraction, or additional Initial metals/anion analysis of the sample
DLC	Decision Level Concentration (Radiochemistry)
EDL	Estimated Detection Limit (Dioxin)
LOD	Limit of Detection (DoD/DOE)
LOQ	Limit of Quantitation (DoD/DOE)
MCL	EPA recommended "Maximum Contaminant Level"
MDA	Minimum Detectable Activity (Radiochemistry)
MDC	Minimum Detectable Concentration (Radiochemistry)
MDL	Method Detection Limit
ML	Minimum Level (Dioxin)
MPN	Most Probable Number
MQL	Method Quantitation Limit
NC	Not Calculated
ND	Not Detected at the reporting limit (or MDL or EDL if shown)
NEG	Negative / Absent
POS	Positive / Present
PQL	Practical Quantitation Limit
PRES	Presumptive
QC	Quality Control
RER	Relative Error Ratio (Radiochemistry)
RL	Reporting Limit or Requested Limit (Radiochemistry)
RPD	Relative Percent Difference, a measure of the relative difference between two points
TEF	Toxicity Equivalent Factor (Dioxin)
TEQ	Toxicity Equivalent Quotient (Dioxin)
TNTC	Too Numerous To Count

Question	Answer	Comment
Radioactivity wasn't checked or is </= background as measured by a survey meter.	True	
The cooler's custody seal, if present, is intact.	True	
Sample custody seals, if present, are intact.	True	
The cooler or samples do not appear to have been compromised or tampered with.	True	
Samples were received on ice.	True	
Cooler Temperature is acceptable.	True	Received same day of collection; chilling process has begun.
Cooler Temperature is recorded.	True	10.1
COC is present.	True	
COC is filled out in ink and legible.	True	
COC is filled out with all pertinent information.	True	
Is the Field Sampler's name present on COC?	True	
There are no discrepancies between the containers received and the COC.	True	
Samples are received within Holding Time (excluding tests with immediate HTs)	True	
Sample containers have legible labels.	True	
Containers are not broken or leaking.	True	
Sample collection date/times are provided.	True	
Appropriate sample containers are used.	True	
Sample bottles are completely filled.	True	
Sample Preservation Verified.	True	
There is sufficient vol. for all requested analyses, incl. any requested MS/MSDs	True	
Containers requiring zero headspace have no headspace or bubble is <6mm (1/4").	N/A	
Multiphasic samples are not present.	True	
Samples do not require splitting or compositing.	True	
Residual Chlorine Checked.	N/A
