# DRAINAGE AREAS OF INDIANA STREAMS

## METHOD

1

by  
Richard E. Hoggatt

Procedures recommended by the Subcommittee on Hydrology of the Federal Inter-Agency River Basin Committee (Bulletin no. 4) were used to determine the drainage areas. The total area of each topographic quadrangle was obtained from Cartographic Tables of the U.S. Geological Survey (Book 5).

---

### ABSTRACT

---

### PRESENTATION OF DATA

Five tables have been prepared for this report.

Drainage areas for all streams in Indiana having a drainage area of at least five square miles have been determined. Also included are drainage areas at many intervening points, such as U.S. Geological Survey stream-gaging stations, partial-record stations and lake gages, National Weather Service river stations, many U.S. and State Highways, several sewage treatment plants, and entrances into and exits out of the State of the larger streams.

#### Table 1

Table 1 (p. 5) lists in downstream order over 7,500 drainage area determination points, starting with the most upstream tributary to the Ohio River in Indiana, and continuing through the most downstream tributary to the Kankakee River in Indiana. The indentation alignment of the stream names in this table indicates tributary arrangement; that is, the left justified stream name is the main stream, with the indentations below it indicating tributaries, and further indentation below the tributaries indicating tributaries to tributaries, etc. If the point of determination is at a U.S. Geological Survey gage, then a national number, assigned by the Survey, is given in the extreme left-hand column. This number is significant in many accounting and computer programs of the Survey.

Table 1 also shows the county in which the point of determination falls, and gives the basin number assigned by the Office of Water Data Coordination, shown in figure 1.

#### Table 2

Table 2 (p. 53) is an alphabetical listing of the Indiana, Ohio, Illinois and Michigan Counties contained in Table 3.

#### Table 3

Table 3 (p. 54) is an alphabetical listing by counties of the drainage areas. The table for each county lists in downstream order all streams in that county. The numbers in the left-hand column are arranged so that the

### INTRODUCTION

When an engineering study is made on a stream, one of the first facts wanted is the drainage area. The drainage area is used as a parameter in analyzing streamflow characteristics for designing hydraulic structures or evaluating the availability of water.

For years, engineers needing drainage areas have made their own determinations from whatever maps or air photographs were available. Complete coverage of Indiana by U.S. Geological Survey topographic maps, scale 1:24,000, was finished in 1965, providing an excellent base from which drainage areas could be determined accurately.

### COOPERATION

The U.S. Geological Survey and the Indiana Department of Natural Resources entered into a cooperative agreement in 1965 to determine the drainage areas of all streams in Indiana having a drainage area of at least five square miles, as well as the drainage area at many intermediate points. Coordination of drainage area lines and tabulations were made with interested State and Federal agencies throughout the project.

most upstream drainage area determination is 1 and the most downstream drainage area is the highest number. These numbers have been shown on the county map opposite the table.

The U.S. Geological Survey topographic map containing the point of determination also is listed. Figure 2 shows the topographic maps for Indiana.

Also listed in table 3 are the section, township, and range for each point.

The drainage area, in square miles, is given to hundredths of a square mile for areas of less than 10 square miles, to tenths of a square mile for areas between 10 to 100 square miles, and is rounded to the nearest mile for areas above 100 square miles.

Several areas, such as the karst area in south-central Indiana and parts of northern and northeastern Indiana in the lake areas, do not have visible drainage systems on the topographic maps. These areas nonetheless are included in the tabulations. Topographic divides were used to delineate these areas in the same manner as they were used for conventional drainage systems. In assigning basins into which these seemingly closed basins contributed, it was assumed that if water were to fill them up like a soup bowl, they would contribute flow in the direction over which water would first flow out of the bowl; that is, at the divide of lowest elevation. In the karst area of southern Indiana, solution channels in the underground rock do not always align themselves with surface divides. Where determination of areas where flow does not contribute directly to surface runoff have been made and they are equal to or greater than five percent of the area into which they contribute, they have been shown under the "NC-OS" column and included in the drainage area figure. The "NC" is an abbreviation for non-contributing. This is a misnomer if taken literally, for the area does contribute indirectly to surface flow through ground-water seepage, or even more directly as in the case of Harrison Springs flowing into Blue River. The "OS" stands for "out of state", which is that portion of the drainage area in square miles, of a stream lying in an adjoining state. The state into which the "OS" area falls has been noted as A, Ohio; B, Illinois; and C, Michigan. Once the area contributed from an adjoining state becomes constant, the last "OS" area noted applies for the remainder of the basin, or until a downstream tributary introduces more area from the adjoining state. As an example of this, the "Wabash River near New Corydon--U.S. Geological Survey Gage (Ohio-Indiana State Line)" contains 251 square miles of drainage area in Ohio. The next entry "Wabash River above tributary" contains 253 square miles in Ohio. This latter entry is the last drainage area from Ohio for the main-stem Wabash River until Loblolly Creek enters. Thus, in table 3, there is no "OS" area shown for the main-stem Wabash River below "Wabash River above tributary" (Jay County) until "Wabash River including Loblolly Creek" (Adams County). The next additional area out of Ohio for the main-stem Wabash is noted for "Wabash River including Mississinewa River" (Miami County). This 285 square miles in Ohio is the sum total of all Wabash River drainage out of Ohio, and is applicable for the main-stem Wabash from the Mississinewa River to the mouth. All "NC-OS" areas have been shown to the same degree of rounding as the drainage area they are shown opposite.

River miles, where available, from river profiles prepared by the Department of Natural Resources have been shown in the last column.

Table 4

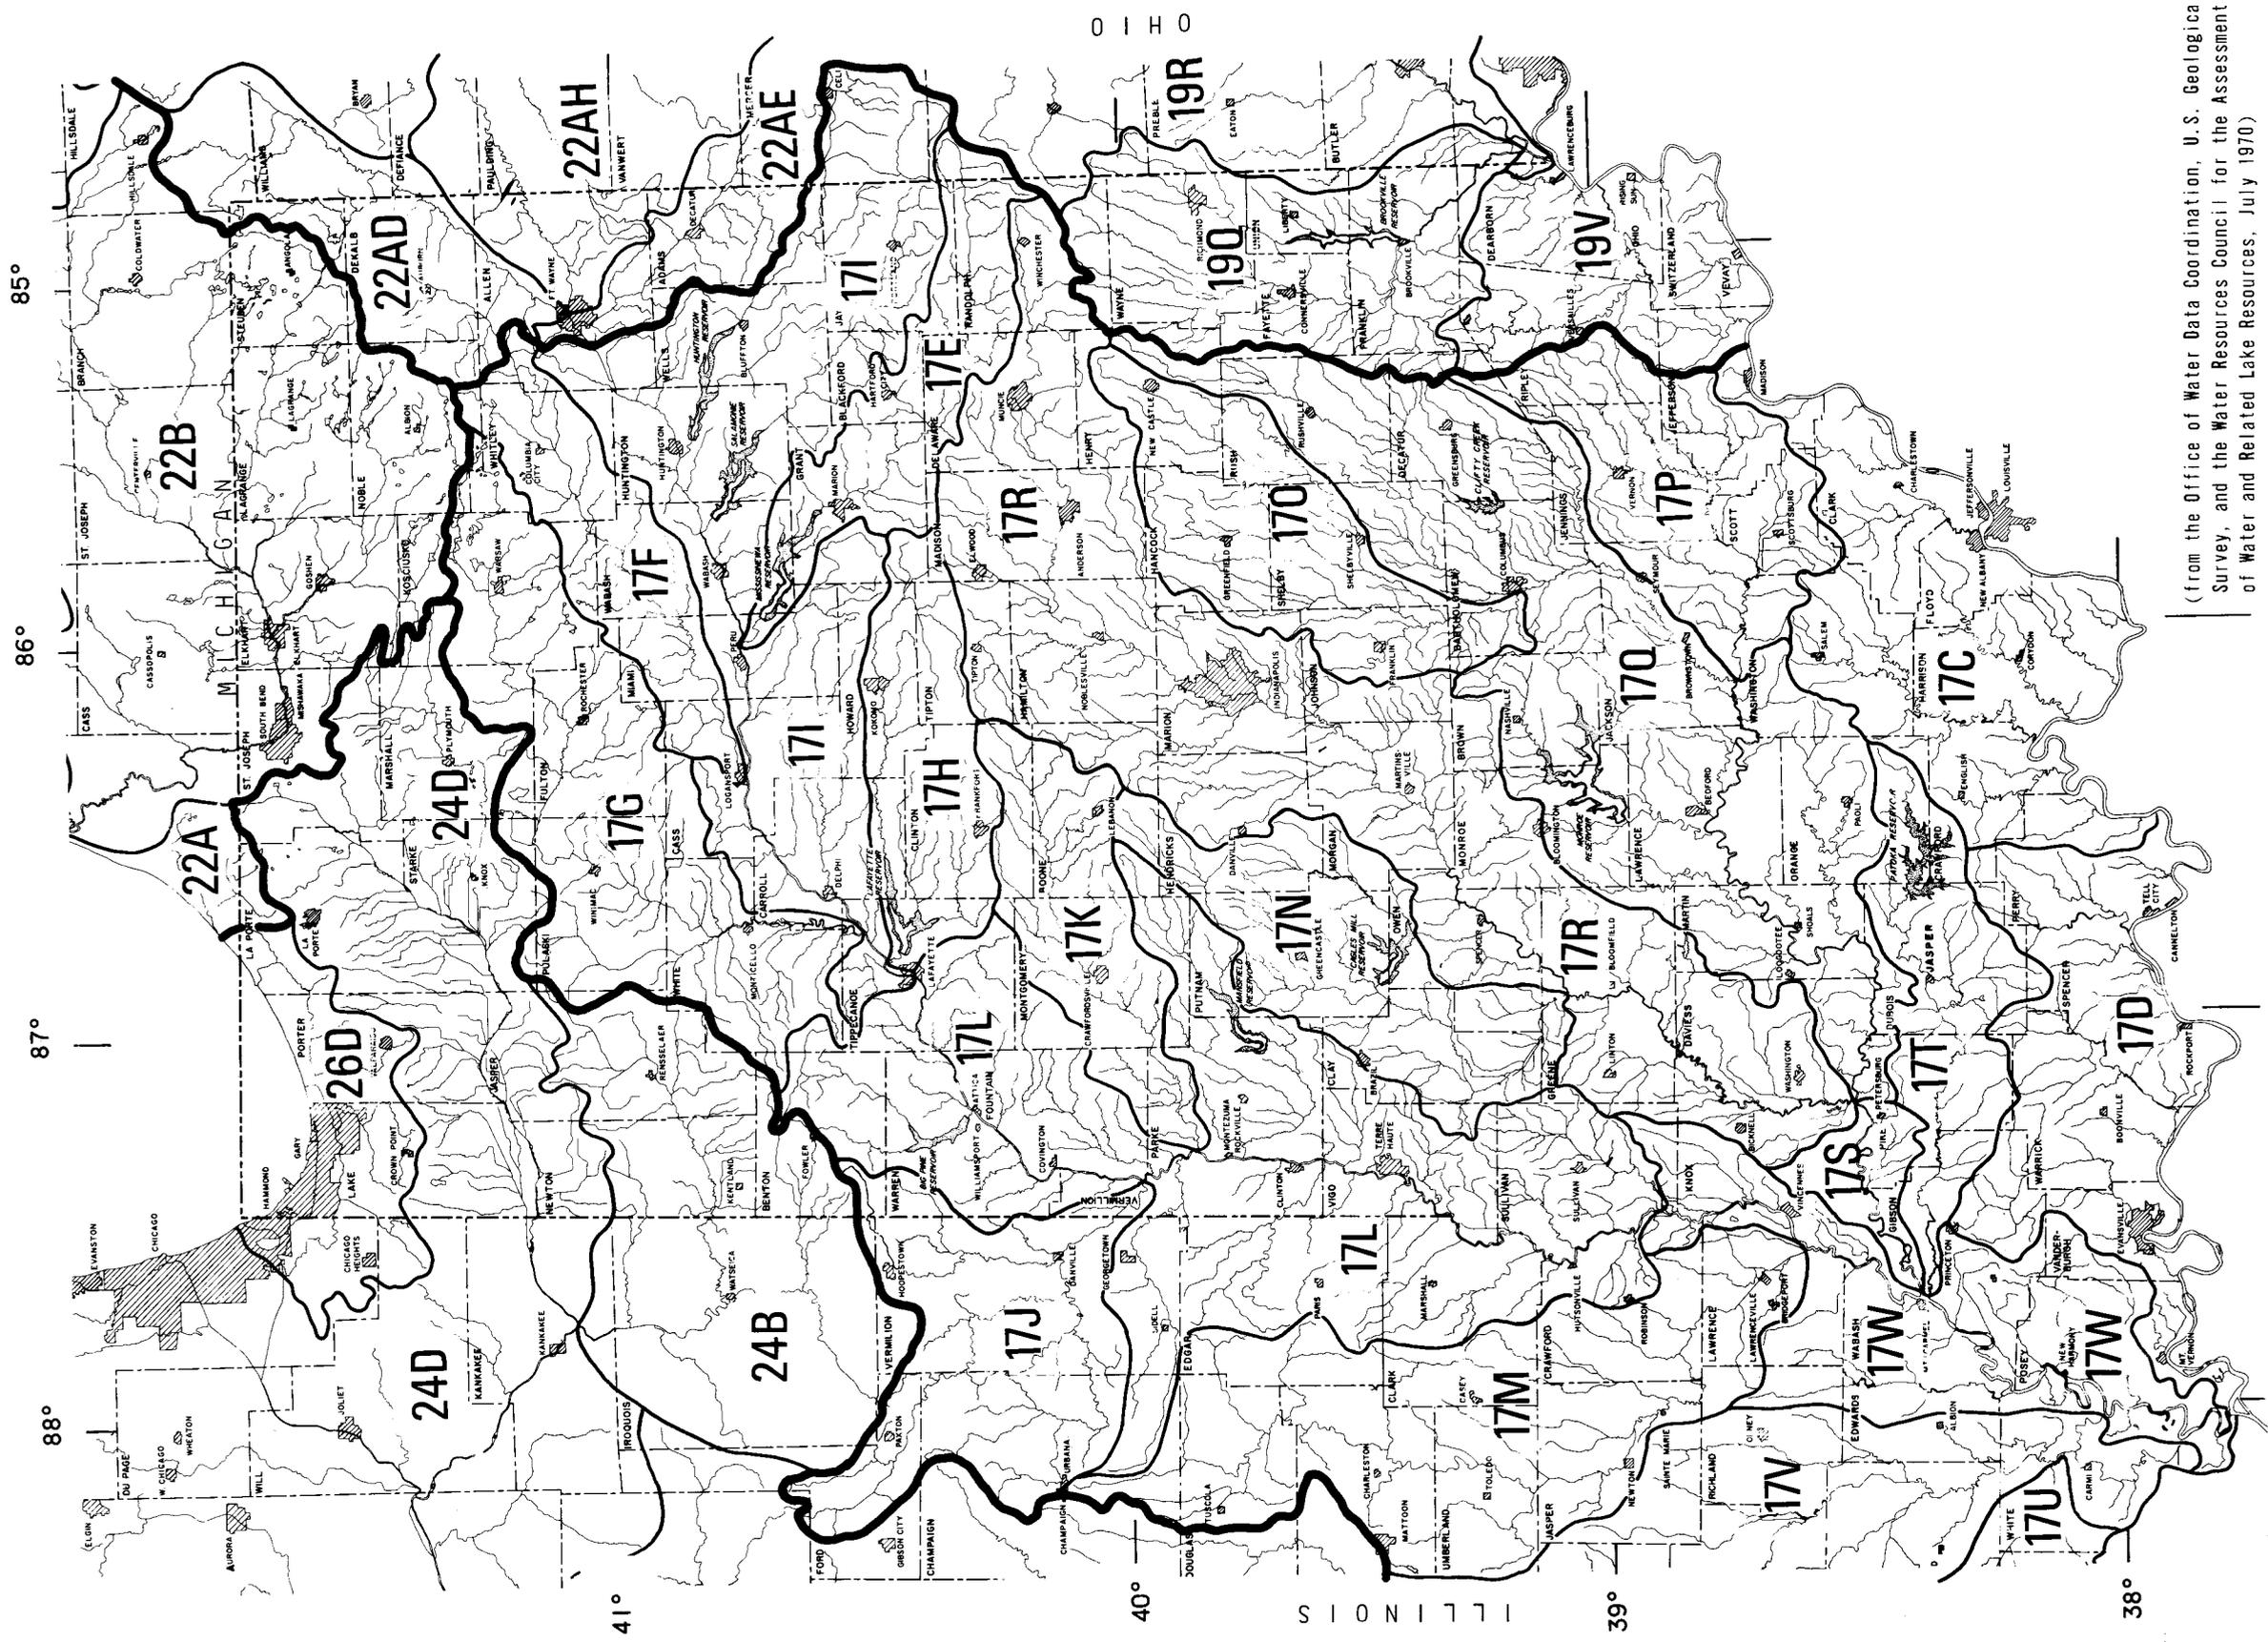

Table 4 (p. 228) lists drainage area determination points in downstream order with drainage areas tabulated for streams draining into, or out of, Indiana from, or into, Ohio, Illinois, and Michigan.

Table 5

Table 5 (see below) is a conversion table for changing English units published herein to the International System of units (SI).

Table 5.--Factors for converting English units to International System units (SI)

Multiply English units	by	To obtain SI units
miles	1.609	kilometres
square miles	2.590	square kilometres

(from the Office of Water Data Coordination, U.S. Geological Survey, and the Water Resources Council for the Assessment of Water and Related Lake Resources, July 1970)

a Entire stream goes into ground

b During low flows the streamflow becomes intermittent at this point

c Lost River is an intermittent flowing stream during low flow in this reach of channel

d Lost River has 172 sq. mi. of intermittent flow and areas which do not contribute directly to surface water runoff above this point

e Lost River has 173 sq. mi. of intermittent flow and areas which do not contribute directly to surface water runoff above this point
