Executive Summary

This report (*Trends in Birth Outcomes and Maternal Characteristics in Indiana: Statistics from the Live Birth Data 1990-2005*) presents detailed statistics on Indiana births according to a variety of characteristics from 1990 to 2005 as reported on the birth certificates. Data are presented on maternal demographic characteristics (including age, education, live-birth order, and marital status), medical services utilization by pregnant women (including prenatal care, cesarean delivery, and induction of labor), and maternal smoking during pregnancy, as well as on selected infant characteristics (birth weight, gestational age, and multiple births). This report also includes trends in low birth weight and preterm birth according to the selected maternal characteristics throughout the 1990-2005 period. These data are presented for all births (all races combined) and for whites, blacks, non-Hispanic whites, non-Hispanic blacks, and Hispanics.

Between 1990 and 2005, multiple birth rate, cesarean delivery rate, and rate of induction of labor increased significantly. Compared to non-Hispanic whites, non-Hispanic blacks had slightly higher multiple birth rates, similar cesarean delivery rates and notably lower rates of induction of labor in 2005. Hispanic women had considerably lower multiple birth rate, similar cesarean delivery rate, and lower rates of induction of labor compared to non-Hispanics.

The increase in key measures of birth outcome, the percentage of preterm and low birth weight (LBW) births, may partly be explained by increases in rates of multiple birth, cesarean delivery, and induction of labor. However, it is important to note that preterm birth rates have also risen among singleton deliveries and among births not delivered by cesarean section. The increase in preterm delivery among singletons during these years was mainly due to an increase in late preterm births (34-36 weeks of gestation).

The wide racial disparity in LBW and preterm birth present in 1990 continues to exist but to a lesser extent in recent years. This gradual narrowing of racial gap between 1990 and 2005, particularly in preterm birth, is mainly due to a significant and notable increase in preterm birth rate among non-Hispanic whites (by 45 percent) and no change among non-Hispanic blacks. The LBW and preterm birth rates among Hispanics, however, were similar to non-Hispanic whites.

Teenage mothers (under 20 years of age) and mothers 35 years of age and older were more likely to have LBW or preterm deliveries than mothers in their twenties and early thirties. Between 1990 and 2005, both LBW and preterm birth rates increased significantly and considerably among all age groups for non-Hispanic white mothers but not for non-Hispanic black or Hispanic mothers. During this period, the proportion of births to teenage mothers declined significantly regardless of race and Hispanic origin whereas births to mothers 35 years of age and older increased noticeably among non-Hispanic white and non-Hispanic black mothers.

For both non-Hispanic whites and non-Hispanic blacks, preterm birth and LBW rates decreased as mother's educational level increased. The exception to this trend was among non-Hispanic white women with less than 9 years of education who had similar or lower LBW and preterm birth rates compared to the college graduates. This least educated group of non-Hispanic white mothers, with favorable birth outcomes,

were less likely to have cesarean delivery, induction of labor, and multiple births, and more likely to receive inadequate prenatal care and reside in non-metropolitan counties compared to more educated mothers. Between 1990 and 2005, the proportion of adult mothers with inadequate education (less than 12 years) remained unchanged among non-Hispanic whites, increased moderately among non-Hispanic blacks and more than doubled among Hispanics.

Low birth weight and Preterm births were lower among married compared to unmarried mothers. However, during the past several years, preterm births increased to a greater extent among the married mothers. Proportion of unmarried mothers was markedly higher among non-Hispanic blacks and Hispanics but increased markedly among non-Hispanic whites and Hispanics over the years.

Women who smoked during pregnancy had notably higher LBW rates and somewhat higher preterm births. The increase in LBW rates observed over the years, however, was more evident among the non-smokers than smokers. The prevalence of smoking during pregnancy declined significantly regardless of race and Hispanic origin but is remarkably lower among Hispanics compared to non-Hispanics and higher among non-Hispanic whites compared to non-Hispanic blacks.

Mothers who received inadequate prenatal care had considerably higher LBW and preterm births than mothers who received adequate or intermediate care regardless of race and Hispanic origin. Between 1990 and 2005, the proportion of mothers who received late or inadequate prenatal care decreased modestly among non-Hispanics but increased significantly among Hispanics.

The wide racial and ethnic disparity in the proportion of birth to teenage mothers, mothers with inadequate education, unmarried mothers, and mothers who received late or inadequate prenatal care continues to exist.

Highlights

- Between 1990 and 2005, births increased for Hispanic women from 2.2 to 9.2 percent, were essentially unchanged for non-Hispanic black women, and declined from 85.6 to 77.3 percent for non-Hispanic white women.
(Table 1, Figures 1-2)
- In 1990, of 1,915 live births for Hispanic women, 27.2 percent were to women who were born outside the U.S. whereas in 2005, 72.1 percent of all Hispanic live births (8,026) were to foreign born mothers.
(Figure 3)
- **Multiple births** rose significantly (by 45 percent) from 2.4 percent in 1990 to 3.5 percent in 2005, a trend similar to the national average during this period. Multiple birth rates were higher among non-Hispanic whites and non-Hispanic blacks and increased similarly and significantly among them in contrast to lower rates and negligible increases over time among Hispanics.
(Table 2, Figures 4-5)
- Multiple birth rates increased with mother's age. In the 2003-2005 period, multiple births rates ranged from 1.7 percent for mothers under 20 years of age to 5.3 percent for those 35 years of age and older. The increase in multiple birth rates over time was evident in all age groups but was present to a greater degree among mothers who were older and those with higher level of education than among the younger and less educated mothers.
(Figures 6-7)
- **Total Cesarean delivery rate** decreased from 21.9 percent in 1990 to 19.8 percent in 1997 followed by a sharp increase to 28.3 percent in 2005. The upward trend in cesarean delivery rates after late 1990's is evident among both non-Hispanics and Hispanics and is comparable to the national trend.
(Tables 2, 5-7, Figures 8, 11)
- In 2005, cesarean delivery rate was 70.1 percent among multiple births compared to 26.8 percent among singletons; the rates increased among both groups (by 27-31 percent) since 1990.
(Figure 12)
- Among singleton births, cesarean delivery rates were higher among older mothers and more educated mothers compared to those who were younger and less educated. Cesarean delivery rates, however, have risen among women in all age and educational groups since late 1990's.
(Figures 13-14)

- Cesarean delivery rates among singletons increased as gestational age decreased. In 2005, cesarean rates ranged from 22.1 percent among births at 40 or higher weeks of gestation to 45.3 percent among the very preterm (less than 32 weeks) births. Cesarean delivery rates increased across all gestational ages in recent years, especially after 1997. Between 1998 and 2005, the rates increased by 36 percent among the very preterm, by 44 percent among the late preterm (34-36 weeks) and by 32 percent among those born at 40 or higher weeks of gestation.
([Figure 15](#))
- The rate of **induction of labor** increased consistently and sharply from 9.3 percent in 1990 to 26.4 percent in 2005.
([Figure 16](#))
- Induction rates continued to be considerably higher among non-Hispanic whites (28.8 percent in 2005) compared to non-Hispanic blacks (19.4 percent) and Hispanics (15.8 percent).
([Figure 17](#))
- Proportion of **live births to teenage women** (under 20 years of age) declined by 24 percent between 1990 and 2003 and remained essentially unchanged at 11.0 percent afterwards.
([Table 2](#), [Figure 19](#))
- Between mid 1990's and early 2000's, births to teenage women declined significantly among both Hispanics and non-Hispanics. The proportion of birth to teenagers in 2005 was almost double among non-Hispanic blacks (19.0 percent) and 36 percent higher among Hispanics (13.3 percent) compared to non-Hispanic whites (9.7 percent), a pattern that has persisted over the years.
([Tables 5-7](#), [Figures 20-21](#))
- Between 1990 and 2005, percentage of births to mothers in their twenties changed slightly whereas births to women in their early thirties increased by 13 percent (to 20.4 percent) and that to older mothers increased by 63 percent (to 10.4 percent). The sharp increase in proportion of **births to mothers 35 years of age or older** was evident among both non-Hispanic whites and non-Hispanic blacks but not among Hispanics.
([Tables 2, 5-7](#), [Figures 19, 22](#))
- In 2005, 14.6 percent of non-Hispanic white mothers had **less than adequate education** (2.8 percent under 20 years of age and 11.7 percent older) compared to 20.2 percent of non-Hispanic blacks and 52.7 percent of Hispanics. Among non-Hispanic black teenagers, however, 20.9 percent had inadequate education compared to 29.2 percent among non-Hispanic white and 45.5 percent among Hispanic teenagers.
([Tables 5-7](#), [Figures 23-24](#))

- Between 1990 and 2005, the proportion of **adult mothers with inadequate education** (less than 12 years) did not change among non-Hispanic whites (11.7 percent in 2005), increased by 30 percent among non-Hispanic blacks (to 16.2 percent), and increased by 123 percent among Hispanics (to 46.6 percent). (Tables 5-8, Figure 25)
- During the period of 1990 to 2005, percentage of **mothers with 16 or more years of education** increased by 71 percent among non-Hispanic whites (to 27.9 percent in 2005) and by 83 percent among non-Hispanic blacks (to 9.7 percent) whereas it declined by 29 percent among Hispanics (to 6.7 percent). The wide racial and ethnic disparity in college educated mothers persisted over the years. (Tables 5-7, Figure 26)
- Between 1990 and 2005, percentage of **fourth- or higher-order births** increased significantly among both Hispanics and non-Hispanics. In 2005, fourth- or higher-order births were 69 percent higher among non-Hispanic blacks (18.6 percent) and 48 percent higher among Hispanics (16.3 percent) compared to non-Hispanic whites (11.0 percent). (Tables 5-8, Figure 27)
- In 2005, the proportion of births to **unmarried mothers** was 40.2 percent, up by 53 percent since 1990. During this period, births to unmarried mothers increased by 67 percent among non-Hispanic whites (to 33.5 percent), by 5 percent among non-Hispanic blacks (to 77.7 percent), and by 63.6 percent among Hispanics (to 54.5 percent). (Tables 5-8, Figure 28-29)
- Between 1990 and 2005, the percentage of women who began **prenatal care in the first trimester** of pregnancy increased by only 2 percent (to 80.4 percent) in Indiana. During this period, early initiation of care increased by 4 percent among non-Hispanic white mothers (to 84.2 percent) and by 9 percent among non-Hispanic black mothers (to 67.0 percent), in contrast to 8 percent decrease (to 64.1 percent) among Hispanics. The wide racial disparity in timely initiation of care, however, persisted over these years and grew even wider between Hispanics and non-Hispanic whites. (Tables 5-9, Figures 30-31)
- In 2005, 24.7 percent of Hispanic women received **inadequate or no care** (based on Kotelchuck index) compared to 23.3 percent of non-Hispanic blacks and 10.2 percent of non-Hispanic whites. While the proportion of mothers receiving inadequate or no care decreased by 13 percent among non-Hispanic whites and by 23 percent among non-Hispanic blacks since 1990, among Hispanics it increased by 14 percent. (Tables 5-8, Figures 32-33)

- **Smoking during pregnancy** declined to 17.9 percent in 2005, slightly lower than the rate in 2004 (18.1 percent) and 33 percent lower than that in 1990 (26.7 percent). The gradual decline in smoking rates observed since 1990 leveled off among non-Hispanic whites after 2002 while it continued to decline among non-Hispanic blacks and Hispanics. In 2005, prenatal smoking rate among non-Hispanic white women was 20.5 percent compared to 14.0 percent among non-Hispanic blacks and 3.3 percent among Hispanics. (Tables 2, 5-8, Figure 34)
- The **low birth weight** (LBW, less than 2,500 grams) rate increased to 8.3 percent in 2005, up from 7.4 percent in 2000 and 6.6 percent in 1990. Between 1990 and 2005, low birth weight rate increased significantly by 34 percent for non-Hispanic whites and by 8 percent for non-Hispanic blacks; the 14 percent increase in LBW rate among Hispanics was not statistically significant. (Tables 2, 5-8, Figures 35-36, 38)
- In 2005, the LBW rate for non-Hispanic blacks was 13.4 percent compared to 7.8 percent for non-Hispanic whites and 6.6 percent for Hispanics. Compared to non-Hispanic whites, the LBW rate of non-Hispanic blacks was 115 percent higher in 1990 and 73 percent higher in 2005. The **narrowing of racial disparity in LBW rate** between 1990 and 2005, however, is not due to an improvement of LBW rate among non-Hispanic blacks but mainly due to a noticeable increase in LBW rate among non-Hispanic whites. (Tables 5-9, Figure 38)
- Between 1990 and 2005, increases were observed for both **very low birth weight** (VLBW, less than 1,500 grams) and **moderately low birth weight** (MLBW, 1,500-2,499 grams) infants. During this period, VLBW rates increased significantly among both non-Hispanic whites (by 37 percent) and non-Hispanic blacks (by 19 percent), whereas MLBW rates increased significantly among non-Hispanic whites (by 33 percent) but not among non-Hispanic blacks. (Tables 2, 5-8, Figure 39-40)
- In 2005, the VLBW rate among non-Hispanic blacks was 3.3 percent compared to 1.3 percent among non-Hispanic whites and 1.2 percent among Hispanics. Racial disparity continues to exist in both VLBW and MLBW rates but is present to a greater degree for the VLBW infants. (Tables 8-9)
- In the 2003-2005 period, the LBW rate was 59.1 percent for multiple births and 6.2 percent for singleton births, up by 13-14 percent among both groups since 1990-1992. (Table 10, Figure 41)
- Between 1990-1992 and 2003-2005, LBW rate for singleton births rose significantly (by 17 percent) among non-Hispanic whites but not among non-Hispanic blacks or Hispanics. (Tables 13-15)

- There was a wide racial disparity in LBW rates among singletons but not among multiple births. In the 2003-2005 period, singleton LBW among non-Hispanic blacks (11.4 percent) was more than double the rate of non-Hispanic whites (5.6 percent), whereas multiple LBW was only 14 percent higher among non-Hispanic blacks compared to non-Hispanic whites.
(Tables 13-15)
- During the 1990 to 2005 period, LBW rates increased significantly among mothers in all age groups except those younger than 18 years of age. The youngest and the oldest mothers were more likely to deliver LBW infants than others. For 2003-2005, the lowest LBW levels were reported for women aged 25-29 years of age; the highest LBW rates were for those less than 18 years of age followed by women 35 years of age and older.
(Table 10, Figure 42)
- In the period of 2003-2005, the LBW rate for non-Hispanic black teenagers was 14.0 percent, more than 50 percent higher than the rate for non-Hispanic whites (9.1 percent) and more than double the rate for Hispanic teenagers (6.6 percent). The racial disparity in LBW grew even wider among adult mothers. Between 1990-1992 and 2003-2005, LBW rates of non-Hispanic whites increased significantly (by 22-31 percent) for all age groups except those under 18 years of age, in contrast to a 7-14 percent increase in rates among non-Hispanic black mothers between 18 and 24 years of age and no significant increase in any age groups among Hispanics.
(Tables 13-15, Figures 43-44)
- Between 1990-1992 and 2003-2005, LBW decreased significantly among mothers with less than 9 years of education and increased significantly among mothers with 9 or more years of education. Mothers with 16 or more years of education had the lowest LBW rates but the sharpest increase in rates (by 44 percent) over time.
(Table 10, Figure 45)
- Among non-Hispanic mothers, LBW rates decreased as mother's education increased to 12 years or more, whereas among Hispanics LBW increased as mother's years of education increased.
(Tables 13-15, Figure 46)
- Hispanic mothers with less than 12 years of education were at a considerable advantage for LBW rates compared to their non-Hispanic counterparts. Non-Hispanic black mothers had higher LBW rates at all levels of maternal education and the racial disparity became wider at higher educational levels.
(Tables 13-15, Figures 47-48)

- Between 1990-1992 and 2003-2005 LBW rates among mothers with more than 12 years of education increased significantly by 43 percent for non-Hispanic whites compared to a 12 percent increase among non-Hispanic blacks. (Tables 13-15, Figure 49)
- Higher LBW rates among unmarried mothers compared to married mothers were noticeable for both non-Hispanic white and non-Hispanic black but not for Hispanic mothers. Between 1990-1992 and 2003-2005, LBW rates among married mothers increased significantly for non-Hispanic whites (by 30 percent) but not among non-Hispanic blacks and Hispanics. In contrast, LBW rates among unmarried mothers increased by 8 percent among non-Hispanics and decreased slightly among Hispanics. (Tables 13-15, Figures 51-52)
- In 2003-2005, the LBW rate of infants born to mothers who smoked during pregnancy was 11.7 percent, more than 60 percent higher than the rate among non-smokers (7.2 percent). The higher LBW rates among smokers compared to non-smokers existed regardless of race and Hispanic origin. (Tables 10-15, Figure 55)
- Between 1990-1992 and 2003-2005, the LBW rates among smokers increased significantly for non-Hispanic whites but not for non-Hispanic blacks and Hispanics. The LBW rates among non-smokers increased significantly by 43 percent for non-Hispanic whites, by 18 percent for non-Hispanic blacks, and by 15 percent for Hispanics. (Tables 13-15, Figure 56)
- The **preterm birth rate** in Indiana rose another 3 percent in 2005, to 13.7 percent of all births compared to 12.7 percent nationwide. The percentage of infants born preterm (less than 37 completed weeks of gestation) has risen 34 percent since 1990 (from 10.2 percent) compared to 20 percent increase in rates at the national level for the same time period. The preterm birth in Indiana, therefore, is rising at a faster rate than the average nationwide. (Table 2, Figure 57)
- Between 1990 and 2005, the proportion of all infants born very preterm (less than 32 completed weeks of gestation) rose by 24 percent (from 1.8 to 2.2 percent) and those born late preterm (34-36 weeks) rose by 48 percent (from 6.9 to 9.8 percent). (Table 2)
- Between 1990 and 2005, preterm rates rose significantly by 45 percent for non-Hispanic whites (to 13.0 percent for 2005) and by 16 percent for Hispanics (to 13.4 percent) but remained essentially unchanged among non-Hispanic blacks (18.9 percent in 2005). (Tables 5-8, Figure 59)

- Between 1990-1992 and 2003-2005 preterm rates increased significantly by 42 percent among infants delivered by cesarean section compared to 18 percent increase among those not delivered by cesarean.
(Table 16, Figure 62)
- The youngest (under 20 years of age) and oldest (35 years and older) mothers were more likely to have preterm delivery than other age groups, regardless of race and Hispanic origin.
(Tables 16, 19-21, Figure 64)
- Between the two periods of 1990-1992 and 2003-2005, preterm birth increased by 25 percent among mothers in their early twenties and by 39-43 percent among mothers in their late twenties and early thirties. Preterm births among mothers in their early thirties increased significantly by 51 percent for non-Hispanic whites (to 13.0 percent in 2003-2005) and by 12 percent for non-Hispanic blacks (to 20.3 percent) in contrast to no significant change for Hispanics (to 12.4 percent).
(Tables 16, 19-21, Figure 65)
- Preterm birth rates decreased as maternal education increased to 12 or more years for both non-Hispanic whites and non-Hispanic blacks. Among Hispanic mothers, however, preterm rates were similar across various educational levels.
(Tables 19-21, Figure 67)
- Between 1990-1992 and 2003-2005, preterm birth increased significantly by 48 percent among non-Hispanic whites mothers with 12 or more years of education compared to a 10 percent increase for non-Hispanic blacks and 22 percent increase for Hispanics in the same educational group.
(Tables 19-21, Figure 69)
- In 2003-2005, preterm rate was 15.4 percent among fourth- or higher-order births compared to 13.5 percent among third-order and 12.2 percent among first and second order births. Since 1990-1992, preterm rates increased to a greater extent for third and fourth- or higher-order births (by 47-49 percent) than for first-order births (by 27 percent).
(Table 16, Figure 70)
- Between 1990-1992 and 2003-2005, preterm rates among married mothers increased by 43 percent for non-Hispanic whites (to 12.1 percent in 2003-2005) and by 17 percent for non-Hispanic blacks (to 17.9 percent) but did not change significantly for Hispanics. In contrast, preterm rates among unmarried mothers increased by 16 percent among non-Hispanic whites and remained essentially unchanged among non-Hispanic blacks and Hispanics.
(Tables 19-21, Figure 72)

- In 2003-2005, preterm birth rates among non-Hispanic and Hispanics were higher by 17-18 percent among mothers who smoked compared to non-smokers. Preterm rates increased significantly since the early 1990's for non-Hispanic white smokers (by 31 percent) but not for non-Hispanic black or Hispanic smokers. Preterm rates for mothers who did not smoke during pregnancy increased to a considerable extent among non-Hispanic whites (by 43 percent) but not among non-Hispanic blacks or Hispanics.
(Table 19-21, Figure 75)
- Diminishing racial disparities in preterm rates in recent years compared to early 1990's in general and across various demographic subgroups is mainly due to an increase in preterm birth rates among non-Hispanic white mothers and not due to decreasing preterm birth rates among non-Hispanic blacks.

Introduction

This report (*Trends in Birth Outcomes and Maternal Characteristics in Indiana: Statistics from the Live Birth Data 1990-2005*) presents detailed statistics on Indiana births according to a variety of characteristics from 1990 to 2005 as reported on the birth certificates. Data are presented on maternal demographic characteristics (including age, education, live-birth order, and marital status), medical services utilization by pregnant women (including prenatal care, cesarean delivery, and induction of labor), and maternal smoking during pregnancy, as well as on selected infant characteristics (birth weight, gestational age, and multiple births). This report also includes trends in low birth weight and preterm birth according to the selected maternal characteristics throughout the 1990-2005 period. These data are presented for all births (all races combined) and for whites, blacks, non-Hispanic whites, non-Hispanic blacks, and Hispanics. Continuous monitoring of low birth weight and preterm births is important in understanding the patterns and changes among various population subgroups because these outcomes are significant predictors of infant mortality and morbidity.

Methods

Data presented in this report were obtained from the birth certificates for all infants born between 1990 and 2005 to mothers who were Indiana residents. The detailed information on maternal and infant characteristics presented in this report is based on the 1989 revision of the U.S. Standard Certificate of Live. This study looks at trends in low birth weight, preterm birth, and a variety of delivery and maternal characteristics over time by race and Hispanic origin of mother and examines the correlates of low birth weight and preterm births including multiple births, cesarean delivery, maternal demographic characteristics (age, education, marital status, live-birth order), prenatal care utilization, and tobacco use during pregnancy across population subgroups.

Yearly statistics on maternal and infant characteristics are reported at the state level for all races combined and for whites, blacks, non-Hispanic whites, non-Hispanic blacks, and Hispanics separately. Data for Hispanic mothers are not further classified by race as the vast majority of women of Hispanic origin are reported as white. To obtain statistically reliable prevalence for low birth weight and preterm births according to the characteristics of interest by race and Hispanic origin of mother, three year moving averages are reported through out the 1990 to 2003 period. In this report, the U.S. Office of Management and Budget race definition of "Black or African American" is referred to as "Black" and ethnicity definition of "Hispanic or Latino" is referred to as "Hispanic".

In computation of percentages (also referred to as prevalence or rate) and percent distributions, births for which a particular characteristic is unknown were subtracted from the figures for total births that were used as denominators before percentages and percent distributions were computed except for data related to prenatal care where the unknown category was included.

The statistical analysis was performed for comparing the prevalence of adverse birth outcomes and selected maternal and delivery characteristics between 1990 and 2005 and for comparing the prevalence of low birth weight and preterm birth by various characteristics of mother and delivery between 1990-1992 and 2003-2005. Text statements pointing to a higher or lower prevalence, percentage, or rate in one period compared to another indicates that the change or the difference in rates is statistically significant, unless otherwise specified. In certain instances, such as among Hispanics in specific subgroups, the change may not be statistically significant despite a noticeable difference in rates, mainly due to the small number of births in those categories. Information on the methods used for statistical significance is presented in the.

Information on the methods used for computation of percentages and rates, on statistical significance, random variation, and stability of rates, and on education of mother and adequacy of prenatal care are presented in the "[Technical Notes](#)". The yearly numbers of all live births by selected characteristics are presented in the Appendix A, and the yearly numbers of low birth weight and preterm births by selected variables are presented in Appendices B and C, respectively.

Results

Race and Hispanic origin of mother

Of all live births in 2005 (n=87,088), 77.3 percent were to non-Hispanic white mothers, followed by 11.2 percent for non-Hispanic black and 9.2 percent for Hispanic mothers. Between 1990 and 2005, proportion of births to Hispanic women more than quadrupled, whereas it declined by almost 10 percent for non-Hispanic whites and remained essentially unchanged for non-Hispanic black women (Table 1, Figures 1-2). The sharp increase in proportion of births to Hispanic women coincides with a noticeable increase in proportion of Hispanic mothers born outside the United States from 27 percent in 1990 to 72 in 2005 (Figure 3).

Multiple births

Multiple birth rate rose by 45 percent from 2.4 percent in 1990 to 3.5 percent in 2005. Multiple birth rates were higher among non-Hispanic whites and non-Hispanic blacks and increased similarly and significantly among them in contrast to lower rates and negligible increases over time among Hispanics (Table 2, Figures 4-5).

Multiple birth rates increased with mother's age. In the 2003-2005 period, multiple births rates ranged from 1.7 percent for mothers under 20 years of age to 5.3 percent for those 35 years of age and older. Multiple birth rates have risen for women in all age groups but the largest growth has been among older mothers. For example, among mothers under 20 years of age the multiple birth rate increased by 17 percent between 1990-1992 and 2003-2005, compared with a 33 percent increase among women in their twenties and 46 percent increase for those in their thirties or older (Figure 6).

In recent years, higher multiple birth rate is evident among older mothers with higher level of educational compared to those with less education which is in contrast to fairly similar rates among these groups in early 1990's. For example in 2003-2005, multiple birth rate of women 30 years of age and older was 5.2 percent for those with more than 12 years of education compared to 3.1 percent for those with less than 12 years of education (Figure 7).

The rise in multiple birth rate in recent years has been associated with a trend in both older age at childbearing and the increasing use of fertility therapies (1-5). Between 1990 and 2005 in Indiana, the proportion of births to mothers 35 years of age and older increased by 65 percent and proportion of adult mothers with more than 12 years of education increased by 36 percent. The rising proportion of older and more educated mothers, especially among non-Hispanic whites, who are more likely to seek fertility treatments may partly explain the increasing overall multiple birth rates.

Multiple births are almost ten times more likely to be low birth weight or preterm (Tables 10 and 16). In 2003, the mortality rate for infants born in multiple deliveries was more than four times higher than that for singletons (6). The increasing

number of multiple births attributable to assisted conception has raised public health concerns regarding multiple gestation-related adverse outcomes. Despite the widespread recognition of this problem, multiple birth rate has continued to increase.

Cesarean delivery

Cesarean delivery rate in Indiana decreased from 21.9 percent in 1990 to 19.8 percent in 1997 followed by a steep increase to 28.3 percent in 2005, a trend comparable to the national rates during this period (Table 2, Figure 8). The continuous escalation in total delivery rate after 1997 is driven by both the increase in primary cesarean rate and the decrease in the rates of vaginal birth after cesarean delivery (VBAC) (Figure 9). Among women with previous cesarean delivery, subsequent deliveries can either be a repeat cesarean or a VBAC. The sharp decline in the rates of VBAC after 1997 implies a corresponding rise in the rate of repeat cesarean deliveries. Between 1997 and 2005, the repeat cesarean rate increased from 72.4 to 93.4 percent (Figure 10), indicating that once a woman has a cesarean delivery, there is more than 90 percent chance that subsequent deliveries will be by cesarean. The increase in primary cesarean deliveries may be associated with non-clinical factors such as demographics, physician practice patterns, and maternal choice (7-9), whereas the steep decline in the VBAC rate may be related to concerns for reported risks associated with VBAC, more conservative practice guidelines, legal pressures, and continued debate regarding the risks and benefits of vaginal birth compared with cesarean delivery (9-12).

The upward trend in cesarean rates in recent years in Indiana is evident among both non-Hispanic and Hispanic mothers and for singleton as well as for multiple births (Tables 2, 5-7, Figures 11-12). Among singleton births, cesarean delivery rates were higher among older mothers and more educated mothers compared to those who were younger and less educated. Cesarean delivery rates, however, have risen among women in all age and educational groups since the late 1990's (Figures 13-14).

Cesarean delivery rates among singletons increased as gestational age decreased. In 2005, total cesarean rate among singletons born at less than 32 weeks of gestation was 45 percent, more than double the rate of 22 percent among those born at 40 and higher weeks of gestation. Cesarean delivery rates, however, increased across all gestational ages in recent years. Between 1998 and 2005, the rates increased by 36 percent among the very preterm (less than 32 weeks), by 44 percent among the late preterm (34-36 weeks) and by 32 percent among the full term births (Figure 15).

Induction of labor

The rate of induction of labor increased consistently and sharply from 9.3 percent in 1990 to 26.4 percent in 2005. Compared to the national rates of induction since 1990, the rates in Indiana have risen to a greater extent and the gap has widened with time (Figure 16). Between 1990 and 2005, induction levels more than tripled among non-Hispanic blacks, increased by almost three fold among non-

Hispanic whites and more than doubled among Hispanics. Induction rates continued to be considerably higher among non-Hispanic whites (28.8 percent in 2005) compared to non-Hispanic blacks (19.4 percent) and Hispanics (15.8 percent) (Figure 17).

Between 1990 and 2005, the rate of induction have risen by more than 93 percent among the very preterm (<32 weeks) deliveries (from 3.6 to 7.0 percent), by 168 percent among late preterm (34-36 weeks) deliveries (from 6.9 to 18.5 percent), and by more than 200 percent among term (37-41 weeks) deliveries (from 8.7 to 28.0 percent) (Figure 18). Induction, whether for a medical indication or elective, has been shown to increase the risk of cesarean delivery in nulliparous women and among those with a prior cesarean delivery (13-15). Increasing induction rates has been suggested to be partly related to an increase in elective inductions (16).

Age of mother

Proportion of **live births to teenage women** (under 20 years of age) declined by 24 percent from 14.6 percent in 1990 to 11.0 percent in 2003 and remained unchanged afterwards (Table 2, Figures 19). Between mid 1990's and early 2000's, births to teenage women declined significantly among both Hispanics and non-Hispanics. The proportion of birth to teenagers in 2005 was almost double among non-Hispanic blacks (19.0 percent) and 36 percent higher among Hispanics (13.3 percent) compared to non-Hispanic whites (9.7 percent), a pattern that has persisted over the years (Tables 5-7, Figures 20-21)

Between 1990 and 2005, percentage of births to mothers in their twenties changed slightly whereas births to women in their early thirties increased by 13 percent (to 20.4 percent) and that to mothers 35 year of age and older increased by 63 percent (to 10.4 percent). The sharp increase in proportion of **births to mothers 35 years of age or older** was evident among both non-Hispanic whites and non-Hispanic blacks but not among Hispanics (Tables 2, 5-7, Figures 19, 22).

Education of mother

In 2005, 18.6 percent of all live births in Indiana were to mothers with inadequate education for their age, up from 16.3 percent in 1990. Among non-Hispanic white mothers in 2005, 14.6 percent had less than adequate education compared to 20.2 percent of non-Hispanic blacks and 52.7 percent of Hispanics. Among non-Hispanic black teenagers, however, 20.9 percent had inadequate education compared to 29.2 percent among non-Hispanic white and 45.5 percent among Hispanic teenagers (Tables 2, 5-8, Figures 23-24).

Between 1990 and 2005, the proportion of adult mothers with inadequate education (less than 12 years) did not change among non-Hispanic whites (11.7 percent in 2005), increased by 30 percent among non-Hispanic blacks (to 16.2 percent), and increased by 123 percent among Hispanics (to 46.6 percent) (Tables 5-7, Figure 25). In contrast, the percentage of mothers with 16 or more years of education increased by 71 percent among non-Hispanic whites (to 27.9 percent in

2005) and by 83 percent among non-Hispanic blacks (to 9.7 percent) whereas it declined by 29 percent among Hispanics (to 6.7 percent) (Tables 5-7, Figure 26).

Live-birth order

In 2005, the first-birth order comprised 38.3 percent of all live births and fourth- or higher-order birth comprised 12.3 percent compared to 41.1 and 9.1 percents in 1990, respectively. Between 1990 and 2005, percentage of fourth- or higher-order births increased significantly among both Hispanics and non-Hispanics. In 2005, fourth- or higher-order births were 69 percent higher among non-Hispanic blacks (18.6 percent) and 48 percent higher among Hispanics (16.3 percent) compared to non-Hispanic whites (11.0 percent) (Tables 2, 5-8, Figure 27).

Births to unmarried mothers

In 2005, the proportion of births to unmarried mothers was 40.2 percent, up by 53 percent since 1990 (Table 2). During this time period, birth to unmarried women increased to a greater extent in Indiana compared to the national average (Figure 28). The proportion of births to unmarried mothers varied widely by race and Hispanic origin. In 2005, births to unmarried mothers was highest for non-Hispanic blacks (77.7 percent), followed by Hispanics (54.5 percent), and non-Hispanic white women (33.5). Between 1990 and 2005, births to unmarried mothers in have risen by 67 percent among non-Hispanic whites, by 5 percent among non-Hispanic blacks, and by 63.6 percent among Hispanics (Tables 5-8, Figure 29).

Prenatal care

Timely initiation of prenatal care does not seem to have improved in Indiana during the last several years. Between 1990 and 2005, the percentage of women who began prenatal care in the first trimester of pregnancy increased by only 2 percent (to 80.4 percent). During this period, early initiation of care increased by 4 percent among non-Hispanic white mothers (to 84.2 percent) and by 9 percent among non-Hispanic black mothers (to 67.0 percent), in contrast to 8 percent decrease (to 64.1 percent) among Hispanics. The wide racial disparity in timely initiation of care, however, persisted over these years and grew even wider between Hispanics and non-Hispanic whites. In 2005, 15.8 percent of non-Hispanic white mothers received late or no prenatal care compared to 33.0 percent of non-Hispanic blacks and 35.9 percent of Hispanics (Tables 5-9, Figures 30-31).

The Adequacy of Prenatal Care Utilization (APNCU) Index (or Kotelchuck Index) is an alternative measure of prenatal timing and adequacy that takes into account not only the initiation of prenatal care but also the number of prenatal visits and gestational age at delivery (17-18). According to this index, the proportion of women who have received less than adequate care in Indiana was 26.6 percent in 2005, showing no improvement since 1995 (Table 2).

In 2005, 24.7 percent of Hispanic women received inadequate or no care (based on Kotelchuck index) compared to 23.3 percent of non-Hispanic blacks and 10.2

percent of non-Hispanic whites. While the proportion of mothers receiving inadequate or no care decreased by 13 percent among non-Hispanic whites and by 23 percent among non-Hispanic blacks since 1990, among Hispanics it increased by 14 percent (Tables 5-8, Figures 32-33).

Smoking during pregnancy

Smoking during pregnancy declined to 17.9 percent in 2005, slightly lower than the rate in 2004 (18.1 percent) and 33 percent lower than that in 1990 (26.7 percent) (Table 2). The gradual decline in smoking rates observed since 1990 leveled off among non-Hispanic whites after 2002 while it continued to decline among non-Hispanic blacks and Hispanics. In 2005, prenatal smoking rate among non-Hispanic white women was 20.5 percent compared to 14.0 percent among non-Hispanic blacks and 3.3 percent among Hispanics (Tables 5-8, Figure 34).

Low birth weight

The low birth weight (LBW, less than 2,500 grams) rate in Indiana increased to 8.3 percent in 2005, up from 7.4 percent in 2000 and 6.6 percent in 1990. Compared to the national average, low birth weight rates in Indiana have been slightly lower in early 1990's but almost the same in recent years (Table 2, Figure 35). Between 1990 and 2005, low birth weight rates increased significantly by 27.1 percent for all births, by 34 percent for non-Hispanic whites and by 8 percent for non-Hispanic blacks; the 14 percent increase in LBW rate among Hispanics was not statistically significant (Tables 5-8, Figures 36-37)

In 2005, the LBW rate for non-Hispanic blacks was 13.4 percent compared to 7.8 percent for non-Hispanic whites and 6.6 percent for Hispanics. Compared to non-Hispanic whites, the LBW rate of non-Hispanic blacks was 115 percent higher in 1990 and 73 percent higher in 2005. The narrowing of racial disparity in LBW rate between 1990 and 2005, however, is not due to an improvement of LBW rate among non-Hispanic blacks but mainly due to a noticeable increase in LBW rate among non-Hispanic whites (Tables 5-9, Figure 38).

Between 1990 and 2005, increases were observed for both very low birth weight (VLBW, less than 1,500 grams) and moderately low birth weight (MLBW, 1,500-2,499 grams) infants. During this period, VLBW rates increased significantly among both non-Hispanic whites (by 37 percent) and non-Hispanic blacks (by 19 percent), whereas MLBW rates increased significantly among non-Hispanic whites (by 33 percent) but not among non-Hispanic blacks (Tables 2, 5-8, Figure 36-37, 39-40). In 2005, the VLBW rate among non-Hispanic blacks was 3.3 percent compared to 1.3 percent among non-Hispanic whites and 1.2 percent among Hispanics. Racial disparity continues to exist in both VLBW and MLBW rates but is present to a greater degree for the VLBW infants (Tables 8-9).

Low birth weight and plurality. In the 2003-2005 period, the LBW rate was 59.1 percent for multiple births and 6.2 percent for singleton births, up by 13-14

percent among both since 1990-1992. For singletons, the LBW rate was 5.5 percent in 1990-1992 and reached a peak of 6.4 percent in 1996-1998 (Table 10, Figure 41).

Between 1990-1992 and 2003-2005, singleton LBW rose significantly (by 17 percent) among non-Hispanic whites but not among non-Hispanic blacks and Hispanics (Tables 13-15). There was a wide racial disparity in LBW rates among singletons but not among multiple births. In the 2003-2005 period, singleton LBW among non-Hispanic blacks (11.4 percent) was more than double the rate of non-Hispanic whites (5.6 percent), whereas multiple LBW was only 14 percent higher among non-Hispanic blacks compared to non-Hispanic whites (Tables 13-15).

Low birth weight and age of mother. During the 1990 to 2005 period, LBW rates increased significantly among mothers in all age groups except those younger than 18 years of age. The youngest and the oldest mothers are most likely to deliver LBW infants. For 2003-2005, the lowest LBW levels were reported for women aged 25-29 years of age; the highest LBW rates were for those less than 18 years of age followed by women 35 years of age and older (Table 10, Figure 42).

In the period of 2003-2005, the LBW rate for non-Hispanic black teenagers was 14.0 percent, more than 50 percent higher than the rate for non-Hispanic whites (9.1 percent), and more than double the rate for Hispanic teenagers (6.6 percent). The racial disparity in LBW grew wider among adult mothers. Between 1990-1992 and 2003-2005, LBW rates of non-Hispanic whites increased significantly (by 22-31 percent) for all age groups except those under 18 years of age, in contrast to a 7-14 percent increase in rates among non-Hispanic black mothers between 18 and 24 years of age and no significant increase in any age groups among Hispanics (Tables 13-15, Figures 43-44).

Low birth weight and education of mother. Between 1990-1992 and 2003-2005, LBW decreased significantly among mothers with less than 9 years of education and increased significantly among mothers with 9 or more years of education. Mothers with 16 or more years of education had the lowest LBW rates but the sharpest increase in rates (by 44 percent) over time (Table 10, Figure 45). Among non-Hispanic mothers, LBW rates decreased as mother's education increased to 12 years or more, whereas among Hispanics LBW increased as mother's years of education increased (Tables 13-15, Figure 46).

Hispanic mothers with less than 12 years of education were at a considerable advantage for LBW rates compared to their non-Hispanic counterparts. Non-Hispanic black mothers had higher LBW rates at all levels of maternal education and the racial disparity became wider at higher educational levels (Tables 13-15, Figures 47-48). Between 1990-1992 and 2003-2005 LBW rates increased significantly by 43 percent among non-Hispanic whites with more than 12 years of education compared to a 12 percent increase among non-Hispanic blacks (Tables 13-15, Figure 49).

Low birth weight and live-birth order. LBW rates were highest among fourth- or higher-order births, followed by first-order births, regardless of race and Hispanic origin of mother (Table 10, Figure 50).

Low birth weight and marital status of mother. Higher LBW rates among unmarried mothers compared to married mothers were noticeable for both non-

Hispanic white and non-Hispanic black but not for Hispanic mothers. Between 1990-1992 and 2003-2005, LBW rates among married mothers increased significantly for non-Hispanic whites (by 30 percent) but not among non-Hispanic blacks and Hispanics. In contrast, LBW rates among unmarried mothers increased by 8 percent among non-Hispanics and decreased slightly among Hispanics (Tables 13-15, Figures 51-52).

Low birth weight and prenatal care. Low birth weight rates among mothers who received no care, as well as among those whose initiation of care was unknown were at least three times of the low birth weight rate among mothers who received care any time during pregnancy (Tables 10, 13-15, Figure 53). Among mothers who received care, low birth weight rates were lowest for those receiving adequate or intermediate care and highest among those who received intensive (adequate plus) care (Tables 10, 13-15, Figure 54).

Low birth weight and smoking status of mother. In 2003-2005, the LBW rate of infants born to mothers who smoked during pregnancy was 11.7 percent, more than 60 percent higher than the rate among non-smokers (7.2 percent). The higher LBW rates among smokers compared to non-smokers existed regardless of race and Hispanic origin (Tables 13-15, Figure 55). Between 1990-1992 and 2003-2005, the LBW rates among smokers increased significantly for non-Hispanic whites but not for non-Hispanic blacks and Hispanics. The LBW rates among non-smokers increased significantly by 43 percent for non-Hispanic whites, by 18 percent for non-Hispanic blacks, and by 15 percent for Hispanics (Tables 13-15, Figure 56).

Preterm births

Preterm birth is a leading cause of infant morbidity and mortality and is associated with nearly one-half of all congenital neurological defects and more than two-thirds of infant deaths (19-20).

The preterm birth rate in Indiana rose another 3 percent in 2005, to 13.7 percent of all births compared to 12.7 percent nationwide. The percentage of infants born preterm (less than 37 completed weeks of gestation) has risen 34 percent since 1990 (from 10.2 percent) compared to 20 percent increase in rates at the national level for the same time period. The preterm birth in Indiana, therefore, is rising at a faster rate than the average nationwide (Table 2, Figure 57).

Between 1990 and 2005, the proportion of all infants born very preterm (less than 32 completed weeks of gestation) rose by 24 percent (from 1.8 to 2.2 percent) and those born late preterm (34-36 weeks) rose by 48 percent (from 6.9 to 9.8 percent) (Table 2, Figure 58).

During the period of 1990 to 2005, preterm rates rose significantly by 45 percent for non-Hispanic whites (to 13.0 percent for 2005) and by 16 percent for Hispanics (to 13.4 percent) but remained essentially unchanged among non-Hispanic blacks (18.9 percent in 2005) (Tables 5-8, Figure 59). The significant rise in preterm birth for non-Hispanic whites is seen among both the very preterm (by 34 percent) and moderately preterm births (by 47 percent) (Table 8, Figure 60-61).

Preterm rates between 1990-1992 and 2003-2005 increased significantly by 42 percent among infants delivered by cesarean section compared to 18 percent increase among those not delivered by cesarean (Table 16, Figure 62).

Preterm birth and plurality. The rise in the incidence of multiple births, which are considerably more likely than singletons to be born preterm, has an important influence on the increasing preterm rate in recent years. The preterm rate for singletons rose by 23 percent from 9.4 percent in 1990 to 11.6 percent in 2005 compared to a 34 percent increase in preterm rate among multiples from 49.2 to 65.9 percent in 2005 (Table 16).

It is important to note that among singleton births, almost all of the increase in preterm births was among infants delivered at 34-36 weeks, or "late preterm"; a small increase (from 1.53 to 1.71 percent) is seen among singleton very preterm births over this period (Figure 63). The increase in late preterm births observed in Indiana, which is also seen at the national level, is of concern because these newborns comprise more than 70 percent of all preterm births and are at higher risk of adverse outcomes compared to infants delivered at higher gestational ages (21-22). A marked change in the proportion of births born at term and post-term has also been observed in recent years. Births in 2005 are notably more likely to be delivered earlier in term, or at 37-39 weeks of gestation, and less likely to be delivered at 40 weeks and later compared to 1990 (Figure 63). The marked shift toward earlier delivery at all gestational ages suggests changes in the use of delivery management techniques such as induction of labor and cesarean delivery (23-25).

Preterm birth and age of mother. The youngest and oldest mothers were more likely to have preterm delivery regardless of race and Hispanic origin (Tables 16, 19-21, Figure 64). Between the two period of 1990-1992 and 2003-2005, preterm birth increased by 25 percent among mothers in their early twenties and by 39-43 percent among mothers in their late twenties and early thirties. Preterm births among mothers in their early thirties increased significantly by 51 percent for non-Hispanic whites (to 13.0 percent in 2003-2005) and by 12 percent for non-Hispanic blacks (to 20.3 percent) in contrast to no significant change for Hispanics (to 12.4 percent) (Tables 19-21, Figure 65).

Preterm birth and education of mother. Preterm birth rates decreased as maternal education increased from 9-11 years to 12 or more years for both non-Hispanic whites and non-Hispanic blacks. Among Hispanic mothers, however, preterm rates were similar across various educational levels (Tables 19-21, Figure 66-67).

Preterm birth rate among non-Hispanic white mothers with less than 9 years of education (10.4 percent in 2003-2005) was the lowest compared to mothers with higher level of education and even than those with 12 or more years of education (Figure 67). Non-Hispanic white mothers with less than 9 years of education were considerably less likely to have cesarean delivery, induction of labor (Figure 68), and multiple births and more likely to be residing in rural (non-metropolitan) counties and receiving inadequate care compared to mothers with higher levels of education.

Between 1990-1992 and 2003-2005, preterm birth increased significantly by 48 percent among non-Hispanic whites mothers with 12 or more years of education

compared to a 10 percent increase for non-Hispanic blacks and 22 percent increase for Hispanics in the same educational group (Tables 19-21, Figure 69).

Preterm birth and live-birth order. In 2003-2005, preterm rate was 15.4 percent among fourth- or higher-order births compared to 13.5 percent among third-order and 12.2 percent among first and second order births. Since 1990-1992, preterm rates increased to a greater extent for third and fourth- or higher-order births (by 47-49 percent) than for first-order births (by 27 percent) (Table 16, Figure 70).

Preterm birth and marital status of mother. Between 1990-1992 and 2003-2005, preterm rates among married mothers increased by 43 percent for non-Hispanic whites (to 12.1 percent in 2003-2005) and by 17 percent for non-Hispanic blacks (to 17.9 percent) but did not change significantly for Hispanics. In contrast, preterm rates among unmarried mothers increased by 16 percent among non-Hispanic whites and remained essentially unchanged among non-Hispanic blacks and Hispanics (Tables 19-21, Figure 71-72).

Preterm birth and prenatal care. Preterm birth rates among mothers who received no care, as well as among those whose initiation of care was unknown were at least three times of the preterm birth weight rates among mothers who received care any time during pregnancy (Tables 16, 19-21, Figure 73). Among mothers who received care, preterm birth rates were lowest for those receiving adequate or intermediate care and highest among those who received intensive (adequate plus) care (Tables 16, 19-21, Figure 74).

Preterm birth and smoking status of mother. In 2003-2005, preterm birth rates among non-Hispanic and Hispanics were higher by 17-18 percent among mothers who smoked compared to non-smokers. Preterm rates increased significantly since the early 1990's for non-Hispanic white smokers (by 31 percent) but not for non-Hispanic black or Hispanic smokers. Preterm rates for mothers who did not smoke during pregnancy increased to a considerable extent among non-Hispanic whites (by 43 percent) but not among non-Hispanic blacks or Hispanics (Table 19-21, Figure 75).

Diminishing racial disparities in preterm rates in recent years compared to early 1990's in general and across various demographic subgroups is mainly due to an increase in preterm birth rates among non-Hispanic white mothers and not due to decreasing preterm birth rates among non-Hispanic blacks. The causes and best management of preterm labor are still not fully understood (20, 26-27).

Technical Notes

Computation of percentages

In computation of percentages (also referred to as prevalence or rate) and percent distributions, births for which a particular characteristic is unknown were subtracted from the figures for total births that were used as denominators before percentages and percent distributions were computed. Rates based on less than 20 births in the numerator are considered unstable and are not reported.

Random variation and stability of rates

In this report, the number of infant births in all counties represents complete counts for that county in the State of Indiana. Therefore, percentages or rates are not subject to sampling error. However, when rates are compared over time, between areas, or among various subgroups, the number of events and the corresponding rates are subject to random variation. That is, the rate that actually occurred may be considered as one of a large number of possible different outcomes (rates) that could have arisen under the same circumstances. As a result, rates in a given population may tend to fluctuate from year to year even when the health of that population is unchanged. The simplest method for addressing the issue of random variation is the computation of 95 percent confidence interval. This interval indicates that it has 95 percent probability of including the true rate.

Random variation in rates based on a relatively small number of events tends to be larger than that for rates based on more frequently occurring events. For this reason, in this report, rates based on fewer than 20 events are not reported. To deal with the stability problem, three years of data are combined to increase the number of events, reduce the effect of random variation, and improve the reliability of rates in individual counties.

Significance testing of differences between two percentages

When testing the difference between two percentages, both percentages must meet the following conditions:

$$\begin{array}{l} B_1 \times p_1 \geq 5 \quad \text{and} \quad B_1 \times q_1 \geq 5 \\ B_2 \times p_2 \geq 5 \quad \text{and} \quad B_2 \times q_2 \geq 5 \end{array}$$

where,

$$\begin{array}{l} B_1 = \text{number of births in the denominator of the first percent} \\ P_1 = \text{the first percent divided by 100} \\ q_1 = 1 - p_1 \end{array}$$

B_2 = number of births in the denominator of the second percent
 P_2 = the first percent divided by 100
 $q_2 = 1 - p_2$

When both percentages meet these conditions, then the difference between the two percentages is considered statistically significant if the resulting Z-score is greater than or equal to 1.96. The formula for the Z-score is:

$$Z = (p_1 - p_2) / \text{SQRT} [(p \cdot q / B_1) + (p \cdot q / B_2)]$$

Where,

p = the pooled percent
 $q = 1 - p$
SQRT= denotes the square root of the expression in brackets
(represents the standard error for the difference between two percentages)

and the pooled percent is:

$$p = (n_1 + n_2) / (B_1 + B_2)$$

where,

n_1 = number of births with the characteristic in the numerator of the first percent
 n_2 = number of births with the characteristic in the numerator of the second percent

Statistical testing for the relative prevalence

The relative prevalence of an outcome, such as low birth weight or preterm birth, among one group compared to the other, such as among blacks compared to whites, are calculated as follows:

$$RP = P_1 / p_2$$

Where,

$P_1 = a / (a + b)$ (prevalence in group 1)
 $P_2 = c / (c + d)$ (prevalence in group 2)
 a = number of births with the selected characteristic in group 1
 b = number of births without the selected characteristic group 1
 c = number of births with the selected characteristic in group 2
 d = number of births without the selected characteristic group 2

The formula for the 95-percent confidence intervals for the relative prevalence (28) is as follows:

$$CI = e^{[\ln(P_1/p_2) \pm 1.96(\text{SQRT}(1/a*b/n_1) + (1/c*d/n_2))]}$$

Where,

$\ln(P_1/p_2)$ is the natural logarithm of the relative prevalence

e denoted that the computed confidence limits are exponentiated

$n_1 = a + b$

$n_2 = c + d$

Birth-weight and gestational age edits

Birth-weight and gestational age edits were performed according to National Center for Health Statistics (NCHS) guidelines (29). Birth weights below 227 grams and above 8,650 grams were considered as unknown. Birth weights within the acceptable range of 227 to 8,650 grams were checked for consistency with gestational age. Gestational age in completed weeks was calculated from the date of last normal menstrual period to the date of birth. The clinical estimate was used for less than three percent of the records in which the date of last menses was missing or when the computed gestational age was either out of the acceptable range of 17 to 47 weeks or inconsistent with the birth weight.

Age-appropriate education of mother

In this report, mother's educational attainment is reported both as number of years of education regardless of mother's age (as reported on the birth certificate) and as an age-appropriate education for mothers under 20 years of age. A mother's education was considered inadequate or less than appropriate-for-age if she was over 18 years of age and had not completed high school or if she was younger and had less than appropriate number of years of education for her age. For example, for a 17-year-old mother, at least 11 years of education was needed to be considered age-appropriate. For teenage mothers, the age-appropriate education is presented to correct for the effect of mother's age on years of education.

Prenatal care utilization

In addition to initiation of the prenatal care as a measure, different prenatal care indices have been developed as alternative measures based on the timing of the prenatal care, the number of prenatal visits, and the gestational age of the infant at birth. In this report, the Kotelchuck Adequacy of Prenatal Care Utilization (APNCU) Index is used (30). This Index includes the adequate plus care category for those women with unexpectedly large number of prenatal visits given the gestational age at delivery and the month prenatal care began.

The Kotelchuck Index does not assess the quality of the prenatal care, simply its utilization. The prenatal care utilization is considered inadequate if care is initiated after the fourth month of pregnancy regardless of the number of visits. Once prenatal care is initiated during the first four months of pregnancy, then the index is classified into inadequate, intermediate, adequate, or adequate plus if the ratio of actual-to-expected number of visits is less than 50 percent, 50-79 percent, 80-109 percent, or 110 percent and more, respectively. The adequate-plus category mainly includes women who are considered at high risk and receive extra prenatal services and have a disproportionately high share of low birth weight infants compared to other categories (31). The prenatal care index is considered unknown for mothers who have missing information or inconsistent values on the initiation of prenatal care, the number of visits, or gestational age, and for mothers with duration of gestation below 20 weeks and above 44 weeks (considered unacceptable values according to Kotelchuck Index).
