The Polis Center
Indiana University-Purdue University Indianapolis
1200 Waterway Boulevard
Indianapolis, Indiana 46202
http://polis.iupui.edu
A school bus lays off its frame in front of the remnants of Henryville, Ind., Elementary School in southern Indiana, March 3, 2012, after a large tornado devastated the town the day before. The Indiana National Guard activated roughly 250 soldiers to come to the community's aid.

Mission Statement
The Indiana Department of Homeland Security will provide statewide leadership, exemplary customer service, and subject matter expertise for the enhancement of public and private partnerships and the assurance of local, state and federal collaboration to continually develop Indiana's public safety capabilities for the wellbeing and protection of our citizens, property and economy.
To learn more about the Indiana Department of Homeland Security visit https://www.in.gov/dhs.

Acknowledgments
The Indiana Department of Homeland Security would like to extend special thanks to The Polis Center at Indiana University-Purdue University Indianapolis for its support in developing the 2019 State Hazard Mitigation Plan. IDHS also recognizes the contributions of the Indiana Silver Jackets, a unique collaboration among federal, state, and local agencies that work together to leverage resources and more effectively address Indiana’s natural hazards.

The Indiana Multi-Hazard Mitigation Plan was developed in collaboration with government, academic, and other private partners for the purpose of preventing, protecting against, responding to, and recovering from natural disasters that may threaten the State’s citizens, infrastructure, and economy.

The federal Disaster Mitigation Act of 2000 provides the legal basis for FEMA mitigation planning requirements for State, local, and tribal governments as a condition of federal grant assistance. Indiana must have a FEMA approved State Multi-Hazard Mitigation Plan to remain eligible to receive federal assistance through the following programs:

- Public Assistance (Categories C-G)
- Hazard Mitigation Grant Program (HMGP)
- Pre-Disaster Mitigation Grant Program (PDM)
- Flood Mitigation Assistance Grant Program (FMA)
- Fire Management Assistance Grants (FMAG)

Since 2008, Indiana has received almost $50,000,000 in Mitigation grant funding through these programs.

The 2019 Indiana Multi-Hazard Mitigation Plan lays the framework for accomplishing one of the Indiana Department of Homeland Security’s top 2019-2020 strategic priorities of expanding mitigation and resiliency in the State of Indiana. This includes expanding statewide collaboration and planning, promoting safety, implementing a statewide mitigation strategy, and strengthening partnerships that impact resiliency.

Throughout this plan, there are boxes highlighting some of Indiana’s best practices in Mitigation. These best practices include projects for the acquisition and demolition of flood prone properties, the construction of residential and community safe rooms to protect citizens during severe weather, collaboration between multiple federal, state, and local agencies and other partners to develop solutions to natural hazard issues, and planning efforts across the State to assess natural hazard risks, identify mitigation opportunities, and help build the resiliency of communities, and the State.

There have been some significant changes to this plan since the last version was adopted back in 2014. Some of these changes include:

- Future climate trends in Indiana are discussed in the State Profile section. Projections are indicating that the State could see an increase in precipitation (6-8%) by mid-century. This will increase the flooding risk in communities throughout the State. There is also projected to be an increase in extreme temperature events (hot and cold). New research is indicating that the most frequent area of tornado activity nationwide (Tornado Alley) is starting to shift eastward due to these precipitation and temperature changes. This shift would bring more frequent severe storms and/or tornadoes to the State.

- Earthquakes - A major update of the earthquake hazard section emphasizes that the threat of earthquakes is not confined to only southwestern Indiana. The entire State needs to be prepared for an earthquake, and five new scenarios in this plan update show the projected effects of an earthquake in various parts of the State.
• New Mitigation Strategies – In collaboration with 63 subject matter experts, seven State agencies, State universities, and other national partners, 91 strategies to help mitigate the risk from natural hazards and build the resiliency of the State have been identified in this plan update. These strategies are all described in section 9 of the plan.

• All data and analyses in the plan were updated for 2019 using the most recent version of FEMA’s Hazus-MH Risk Assessment software, along with other GIS analyses, and updated information from all 92 counties.

The Indiana Multi-Hazard Mitigation Plan and the Indiana Department of Homeland Security’s planning process comply with all applicable Federal statutes and regulations, and the State will amend the plan as necessary to reflect changes in State and Federal laws and statutes as required in 44 CFR 201.1 - 7.
1 Introduction

The Indiana Standard Hazard Mitigation Plan (SHMP) seeks to examine the disasters that have impacted the state, identify high-risk communities and areas of vulnerability, and explore emerging threats. It is the basis by which the State encourages local jurisdictions to adopt sound mitigation principles and activities, and allows the State to provide technical assistance and funding opportunities to help communities become more resilient to disasters. All of the assistance provided through federal and state funding has been, and will continue to be, granted to local and state agencies within the scope and guidance provided as required by federal, state, and local rules, laws, and regulations.

In the past decade, Indiana has received 9 federal disaster declarations, which have impacted 87 of its 92 counties (Figure 1). The most recent disaster (DR-4363) was declared on May 4, 2018 after melting snow and heavy rain resulted in extensive floods in northwestern Indiana and along the Ohio River in southern Indiana after a severe winter storm resulted in the second highest calendar day snowfall for Indianapolis. Some areas had 4 to 7 inches of precipitation above normal in February. It was the wettest February on record in Evansville.

*Figure 1. Federal Disaster Declarations (2008-2018)*

**Decade of Disasters (2008-2018)**

**DR-4363:** Severe storms and flooding causing extensive and record flooding along the Yellow, Kankakee and Iroquois Rivers.

**DR-4173:** Severe winter storm and snowstorm with the second highest calendar day snowfall for Indianapolis, 11.4”, since records began.

**DR-4058:** Severe storms, straight-line winds, and tornadoes. 14 deaths due to tornadoes, including an EF4 tornado that destroyed a school.

**DR-1997:** Severe storms, tornadoes, straight-line winds, and flooding, including up to 2” hail, EF0 to EF2 tornadoes.

**DR-1832:** Severe storms, tornadoes and flooding, including an EF3 tornado.

**DR-1828:** Severe winter storm with both ice and snow accumulations up to 8”.

**DR-1795:** Severe storms and flooding with wind gusts up to 70mph.

**DR-1766:** Devastating flood with over $150 million dollars in disaster dollars.

**DR-1740:** Significant flooding in Northern Indiana with record flowing along the Tippecanoe River.
In the event of a federally declared disaster, individuals, families, and communities may be eligible for financial assistance to help with critical expenses. Assistance may be categorized as Individual Assistance (IA), Public Assistance (PA), or Hazard Mitigation Assistance.

The following types of assistance may be available in the event of a disaster declaration:

- **Individuals & Households Program**: Provides financial and direct services to eligible individuals and households affected by a disaster who have uninsured or underinsured necessary expenses and serious needs.
- **Housing Assistance**: Provides assistance for disaster-related housing needs.
- **Other Needs Assistance**: Provides assistance for other disaster-related needs such as personal property, transportation, and medical expenses.
- **Public Assistance**: Disaster grant assistance available for communities to quickly respond to and recover from major disasters or emergencies declared by the president.
  - **Emergency Work (Categories A-B)**: Work that must be performed to reduce or eliminate an immediate threat to life, to protect public health and safety, and to protect improved property that is significantly threatened due to disasters or emergencies declared by the president.
  - **Permanent Work (Categories C-G)**: Work that is required to restore a damaged facility, through repair or restoration, to its pre-disaster design, function, and capacity in accordance with applicable codes and standards.
  - **Section 406 – Public Assistance Program**: Provides discretionary authority to fund mitigation measures in conjunction with the repair of disaster-damaged facilities.
- **Community Development Block Grants**: Provides grants to help cities, counties, parishes, and states to recover from presidentially declared disasters, especially in low- and moderate-income areas. This program is administered by the Indiana Housing and Community Development Authority (IHCDA).
- **Assistance for Farmers and Ranchers**: Provides financial assistance to eligible producers affected by natural disasters through the United States Department of Agriculture (USDA) and Small Business Administration (SBA) programs.
- **Hazard Mitigation Assistance**: Grant program providing assistance to states and local governments to implement long-term hazard mitigation measures after a major disaster declaration.

The majority of disaster assistance is provided via low-interest disaster loans, which are available after a disaster for homeowners and renters from the US Small SBA to cover uninsured property losses. These loans are available to individuals for the repair or replacement of homes, automobiles, and damaged personal property; they are also available to businesses for property loss and economic injury. SBA disaster loans can be available for federally and non-federally declared disaster events.

At the time of this writing, 2018 disaster and related information were not yet finalized. In order to compare annual information, this section includes disaster information for 2008 through 2017.

Figure 2 illustrates (by year) how federal dollars were split between IA and PA. There were no federal dollars approved or obligated in 2010, 2013, 2015, 2016, and 2017.
Figure 2. Federal Disaster Assistance by Type for Indiana Disasters (2008-2017)

* Dollars Approved: assistance dollars approved but not necessarily disbursed
** Dollars Obligated: funds made available to the state via electronic transfer following the Federal Emergency Management Agency’s (FEMA) final review and approval of PA projects

Note about Figure 2 Chart:
- Total Individual Assistance includes Individuals & Household Program (IHP), Housing Assistance (HA), and Other Needs Assistance (ONA).
- Total Public Assistance includes Public Assistance, Emergency Work, and Permanent Work.

INDIANA BEST PRACTICE
The Indiana Department of Natural Resources (IDNR) developed the Indiana Floodplain Information Portal (INFIP) as a digital repository for hydrologic and hydraulic models and floodplain maps. This information is used to update Flood Insurance Studies (FIS) and Flood Insurance Rate Maps (FIRMs) in a digital format. The new flood maps allow the State and local jurisdictions to better administer their flood management programs. It is available at https://dnrmaps.dnr.in.gov/appsphp/fdms/.

Total obligated Hazard Mitigation Grant Program (HMGP) funding between 2008 and 2017 totaled $40,257,203. The majority of the total obligated in the past decade ($25.2 million) was for assistance related to catastrophic flooding in 2008 (DR-1766). The State also received $267,173.75 in 2008-09 from the Flood Mitigation Assistance (FMA) program. Total obligated Pre-Disaster Mitigation (PDM) funding between 2008 and 2017 totaled approximately $9,800,000. As can be seen in Figure 3 below, HMGP
funds, resulting from disaster declarations, have significantly decreased, while PDM funds have started to increase. This is, in part, a result of the government’s emphasis on pre-disaster mitigation.

Figure 3. HMGP and PDM Funding Obligated for Indiana Disasters (2008-2017)

The Indiana State Disaster Relief Fund (SDRF) is a state disaster recovery fund for events that have seriously impacted communities, but that do not rise to the level of a federal declaration. Although established in 2003 to provide infrastructure damage assistance, the Indiana SDRF was not funded until 2007. This funding is very limited as it is tied to the public safety fund and is dependent on the state’s fireworks sale. In 2007, the SDRF was expanded to provide Individual Assistance for homeowners and renters whose primary residence was damaged/destroyed. Table 1 provides a summary of total SDRF program costs since 2007.

The goals of the SHMP include the following:
- Identify areas of vulnerability throughout the state and estimate the cost and magnitude of potential disasters
- Establish strategies and priorities to mitigate risks to citizens and property from natural, technological, and human hazards
- Identify specific mitigation projects to pursue for identified hazard
- Guide each Indiana Department of Homeland Security (IDHS) district in its risk management priorities and activities
- Establish eligibility for future mitigation project funds
Located in the Great Lakes region of the United States, Indiana is the 17th most populous state and 38th in terms of land area. It is comprised of 92 counties, 681 census places, 16 metropolitan statistical areas (MSA), and 25 micropolitan statistical areas. The Indiana Department of Homeland Security (IDHS) has divided the state into 10 districts (Figure 4) to more effectively coordinate disaster activities such as response, damage assessment, preparedness, and outreach and education.

### 2.1 Geography and Topography

In terms of land area, Indiana is one of the smallest states west of the Appalachian Mountains, but its topography varies significantly from the northern portion of the state to the southern portion. The northern two-thirds are characterized primarily by flat plains and numerous small lakes, and the effect of Lake Michigan often induces heavy winter precipitation, especially snowfall. In contrast, the unglaciated southern region is characterized by rolling hills, caves, and waterfalls. Underlying limestone produces soils with poor water retention capacity, making it difficult for crops to grow and develop without frequent rains. The growing season is longer in the southwest part of the state where asparagus, strawberries, and melons are grown commercially.

The Central Till Plain is primarily drained by the Wabash River system and produces the state’s highest crop yields. Corn, soybeans, vegetables, and fruit are grown throughout the Wabash River Basin, but the risk of frost, late spring freezes, and severe winter kill must be considered for mitigation purposes. Figure 5 illustrates Indiana’s physiographic landscape. Figure 6 shows the state’s perennial streams while Figure 7 shows the Hydrologic Unit Code (HUC) 8 basins.

2.2 Climate

Indiana is in the hot-summer humid continental climate zone, with large seasonal temperature differences. The state has four distinct seasons with cold winters and hot and humid summers. Due to latitude differences, northern Indiana tends to be cooler than southern Indiana. Precipitation typically averages 40 inches per year, increasing from north to south. Indiana’s climate is affected by both the Gulf of Mexico, with warm and humid air, and the jet stream, which brings polar air from Canada.

The state is impacted by the El Niño-Southern Oscillation (ENSO). ENSO is a recurring climate pattern involving changes in the temperature of waters in the central and eastern tropical Pacific Ocean. ENSO has three phases: El Niño, La Niña, and neutral. During El Niño, the central and eastern tropical Pacific Ocean water surface warms while during La Niña the water surface cools. During the neutral phase, the tropical Pacific sea surface temperatures are close to average. Indiana winters during El Niño tend to be drier than normal while La Niña winters tend to be wetter than normal. Looking at 24 El Niño winters since 1950, the average winter temperature in Indiana was warmer than normal in 11 of them and colder than normal in 13 of them. However, if a particularly strong El Niño occurs, then Indiana winters tend to be warmer than normal.

The state is subject to extreme weather such as thunderstorms and tornadoes, especially in the spring. Spring is the wettest season, bringing with it floods, while fall tends to be drier.

2.2.1 Past and Current Climate

Figure 8 through Figure 10 show the average temperatures and precipitation per month in three Indiana cities. Mishawaka is located in northern Indiana near the Michigan border, Evansville is in the southwestern tip of the state, while Indianapolis is centrally located.

Average high temperatures in January range from the low 30s in the northern part of the state to the low 40s in the southern part. July highs range from the low 80s to the upper 80s. January is the coldest month of the year while July is the warmest.

*Figure 8. Mishawaka Climograph (Your Weather Service, 2018)*
Average annual precipitation ranges from 41 inches in Mishawaka to 45 inches in Evansville. May is typically the wettest month of the year, but the months of greatest flood frequency in Indiana are from January through June (see Figure 11). Flash floods, however, are most frequent from May to July (see Figure 12).
Tornadoes are a common occurrence in Indiana. Over 1700 tornadoes have been reported in the state from 1950 to 2017, with the majority of those from April to June (see Figure 13).
Indiana is subject to other storm events, besides flooding and tornadoes. Table 4 shows the top ten types of events from 1996 through 2017 according to the National Climatic Data Center (NCDC).

</tbody>
</table>

Drought is a period of unusually dry weather that persists long enough to result in negative impacts such as crop damage, decreasing water supply, and/or the ignition of wildfires. It is a normal, recurrent feature of climate that occurs in virtually all climate zones (National Oceanic and Atmospheric Administration, 2018). Drought is unique from other hazards, which can make it more challenging to manage and plan for effectively. It is unique because it often develops gradually, can last for months or years, and the spatial extent varies depending on the drought. There are cases, though, when drought develops relatively quickly and lasts a very short period of time, exacerbated by extreme heat and/or wind (i.e., flash drought).

Even though recent decades have trended towards wetter conditions in Indiana, drought has been a prominent hazard known to impact the state (Figure 14). The drought of record for the state was in the early 1930s, while the most recent drought to impact Indiana was a flash drought in 2012. Even though the drought in 2012 pales in comparison to the droughts in the early 1900s, there were still significant negative impacts to Indiana in 2012. Indiana’s agriculture saw a significant impact, with poor corn and
soybean conditions, decreased crop yields (lowest corn yield in the last 75 years), issues with aflatoxin in corn, and Indiana’s crop insurance payouts topped $1 billion for drought impacts on corn, soybeans, and wheat. In addition, water restrictions were implemented in major metropolitan areas such as Indianapolis, and burn bans were in effect in 84 of Indiana’s 92 counties by July 2012 (National Drought Resilience Partnership, 2018).

*Figure 14. Values for the Palmer Drought Severity Index for Indiana, 1895 – 2017*

<table>
<thead>
<tr>
<th>Palmer Drought Severity Index (PDSI)</th>
</tr>
</thead>
<tbody>
<tr>
<td>The PDSI is the most prominent index of meteorological drought used in the United States for long-term drought monitoring and research. It uses readily available temperature and precipitation data to estimate relative dryness. It is a standardized index that spans -10 (dry – yellow bars) to +10 (wet – green bars). PDSI calculations are based on precipitation and temperature data as well as the local available water content of the soil.</td>
</tr>
<tr>
<td>Future model projections for precipitation changes are less certain than those for temperature, but in general, average precipitation is likely to occur and increases in the frequency and intensity of extreme precipitation (i.e., heavy precipitation and stretches of dry weather) are expected across the Midwest. Some regional climate models project increased spring precipitation, but decreased summer precipitation, particularly in the southern portions of the Midwest. The average number of days without precipitation is expected to increase in the future, which could lead to agricultural drought and suppressed crop yields. Figure 15 shows the projected change in the average maximum number of consecutive days each year with less than 0.01 inches of precipitation for the middle of the current century (2041 – 2070) relative to the end of the last century (1971 – 2000) across the Midwest under continued emissions. An increase in this variable has been used to indicate an increase in the chance of drought in the future (USGCRP, 2018).</td>
</tr>
</tbody>
</table>
2.2.2 Future Climate Trends

Scenarios are used to explore how much humans are likely to contribute to future climate change given uncertainties in factors such as population growth, economic development, and development of new technologies. In order to calculate how human activities could affect the climate system, scientists insert greenhouse gas concentrations, pollution, and changes in land cover to their models. These factors influence the Earth’s climate. How much emissions and land use change scientists should add depends on future social and economic development. This information is provided by scenarios produced by integrated assessment models (CICERO, 2018).

Four emissions pathways are commonly used in future climate modeling, ranging from significantly reduced emissions levels to continuing on the current-day high emissions trajectory. While all of these scenarios are considered possible, the lowest emissions scenario is highly unlikely.

Figure 16 shows a multimodel simulated time series from 1900 to 2100 for the change in global annual mean surface temperature relative to 1901-1960 for a range of the Representative Concentration Pathways (RCPs). These scenarios account for the uncertainty in future emissions from human activities, as analyzed with the 20+ models from around the world used in the most recent international assessment. The mean (solid lines) and associated uncertainties (shading, showing ±2 standard deviations across the distribution of individual models based on the average over 2081-2100) are given for all of the RCP scenarios as colored vertical bars. The numbers of models used to calculate the multimodel means are indicated.

According to the Indiana Climate Change Impacts Assessment (IN CCIA) from 2018 (Widhalm, et al., 2018), Indiana weather is predicted to change this century. The main findings are listed below:

- Temperatures are projected to rise about 5-6°F by mid-century.
- The number of extremely hot days will rise.
- Extreme cold events will decline.
- The frost-free season will lengthen.
2.2.2.1 Temperatures

The IN CCIA indicates that Indiana has warmed 1.2°F since 1895 (see Figure 17) and temperatures will rise by about 5°F to 6°F by mid-century. This has multiple impacts for Indiana, including changes to the timing and length of the frost free season, and the occurrence of temperature extremes. These shifts will impact air quality, extend the growing season and the allergy season, and create more favorable conditions for some pests and invasive species.

Indiana’s growing season is expected to increase by 35 days for the northern part of the state, 33 days for the central part of the state, and 30 days for the southern part of the state (see Figure 18).

Warming temperatures in the winter months will affect the types of plants and pests that can thrive in Indiana and alter the amount of energy needed to heat and cool homes and businesses.

2.2.2.2 Precipitation

Since 1895, average annual precipitation in Indiana has increased by about 15%, or about 4.5 inches, based on a linear trend. This trend is projected to continue, though the type of precipitation and when it falls are changing and will continue to do so.

The southern and west-central regions of the state have observed the largest increases in precipitation, while the east-central and northeast regions observed the smallest. Spring and fall increases were smallest in the north and largest in the south. The opposite was true in summer, when increases were larger in the north and west.
Annual precipitation is projected to continue to increase. It is estimated that by mid-century, Indiana will see about 6 to 8% more rainfall than in the recent past. However, this increase will not be spread evenly throughout the year. Winter and spring are expected to see substantial increases in precipitation (13 to 20 percent), and more falling as snow. There is high agreement among climate models for the winter and spring seasons. Increased precipitation will create challenges for flood control and storm water management. Summer and fall precipitation projections are less confident across models, with the average projection showing modest declines. Declining warm season rainfall coupled with higher temperatures is expected to increase water stress and lead to possible water shortages for crops, drinking water and wildlife.

With increasing temperatures, it is expected that rain will replace snow in the cold season. Fewer snow days would save municipality and state funding for plowing and salting roadways. However, wetter winters and springs will increase the risk of flooding and combined sewer system overflows, resulting in decreased water quality.

### 2.2.2.3 Extreme Events

While the annual number of extremely hot days between 1960 and 2013 has not changed, it is expected to rise significantly in the future. By mid-century, it is projected that the hottest temperature of the year will rise by about 8°F. These higher temperatures can cause roadways and pavement to warp and buckle in addition to causing heat-related illnesses among people and pets.

Extreme rainfall events (more than 0.86" of rain in a day) have increased in the past century and this is expected to continue. The northwestern part of the state has experienced the largest increase. Rainfall totals during these events are also increasing. The events contributed to soil erosion and nutrient runoff, affecting both water quality and crop productivity.
In the Midwest (which includes Indiana), there has been a 53% increase in heavy rain events (defined as 2-day rainfall totals with a 5-year return period) from 1958 to 2016. During the same time frame, there has been a 42% increase in the amount of rain falling in heavy downpours. See Figure 21 for the change in heavy precipitation by region of the United States (USGCRP, 2017).

In addition to extreme temperatures and rainfall evidence, new research appears to demonstrate that while “national annual frequencies of tornado reports have remained relatively constant, [...] significant spatially-varying temporal trends in tornado frequency have occurred since 1979” (Gensini & Brooks, 2018). Indiana is one of the states showing this upward trend. Historically, tornadoes occurred most frequently in the Southwest, over less populated areas. This increased frequency and spatial varying will put more residents and property at risk, while increasing response and recovery costs.

2.3 Natural Hazards

Indiana’s unique geography, geology, and meteorology make it vulnerable to earthquakes, floods, tornadoes/high winds, severe winter storms, droughts, and extreme temperatures. Incidents involving other natural hazards, such as subsidence, landslide, and wildfire have been rare or localized and unreported, making the risk to the state as a whole difficult to assess.

According to the United States Geological Survey (USGS) and IDNR, there has been no documented subsidence in urbanized areas of the state.

Most of the underground coal mines and karst topography that would cause these subsidence events are located in southern and south central rural farming areas. However, these areas have begun to convert to residential or mixed commercial developed areas due to the abandonment or reduction of coal activities in the state and the pressures of increased development throughout the first decade of the 21st century. The increased development will likely cause more and more incidents of subsidence affecting the built environment. Where karst topography and reclaimed mines once created sinkholes in
pasture or farm fields, they will now impact a residential subdivision or commercial park. Lands once associated with mining have additional hazards associated with abandoned tunnels and entrances, acidic runoff, and the infiltration of carbon dioxide gas into lower levels of buildings.

Also of note but not individually addressed, are the natural hazards, such as hail, that are associated with tornadic-type storms. The SHMP addresses these within the broader category of severe thunderstorms and tornadoes.

Indiana had the 6th highest number of properties affected by hail damage in 2017 with 456,215 properties or 18% of all properties. Ahead of Indiana were Texas, Illinois, Missouri, Minnesota, Oklahoma, and Kansas (Insurance.com, 2018).

### 2.4 Demography

According to the 2016 American Community Survey (ACS) 5-year estimate, Indiana is the 17th most populous state in the nation with 6,589,578 people and a population density of 181 people per square mile. The most populous city is the capital of Indianapolis. Table 5 lists the ten counties with the highest total population.

Figure 23 on the following page shows Indiana’s population pyramid, which illustrates the distribution of the state’s population in terms of age groups and gender. Population pyramids are used to analyze growth or decline of fertility, mortality, and migration within the specified area.

Indiana’s population pyramid is relatively stable indicating slow population growth, long life expectancy, and low infant mortality. It shows the same general shape as a population pyramid of the United States. The slight increase in population from 50 to 59 years represents the tail end of baby boom generation, which is defined as the population cohort born between 1946 and 1964. This increase will continue to travel upward as that population ages.
Most of Indiana’s counties exhibit a population distribution similar to the state’s; however, there are some areas (see the charts on the following page) with atypical distributions, indicating the presence of populations that may require special consideration in terms of disaster mitigation.

In 2013, IDHS, The Polis Center, and Indiana University (IU) collaborated to develop a comprehensive Disaster-Resistant University (DRU) plan for all eight of the university’s campuses. This was one of the first DRUs to include campus-specific, Level 2 Hazus analyses for flood and earthquake.

Figure 24 shows the population pyramid for the City of West Lafayette. The spike for the population aged 20 to 24, which accounts for more than 30% of the city’s total population, is due to the significant student population at Purdue University.

Figure 25 shows the pyramid for the Town of Westville. The male population aged 20 to 39 far surpasses the female population in the same age group. This is because the town is home to the state-operated Westville Correctional Facility, a prison for adult males.
Figure 24. City of West Lafayette Population Pyramid

Figure 25. Town of Westville Population Pyramid
The State of Indiana is becoming increasingly diverse, comprising many cultures and sub-cultures, which are important to consider in mitigation planning. Figure 26 shows the state’s racial composition as estimate for 2016.

Figure 26. Indiana’s Racial and Ethnic Composition

2.5 Population Change

According to the US Census Bureau’s Estimates of the Components of Resident Population Change (2010-2016), Indiana’s population grew by more than 172,180 or 2.7%, well above the average growth of the Midwest. Hamilton County had the most significant increase (10.4%), and Pulaski County had the most significant decrease (-3.7%) in population. Figure 27 on the following page illustrates population change from 2010 to 2016 for each county.

Populations grow or decline through migration and natural increase, and often these two components offset each other. Because international migration data was not as reliable as domestic migration data, this plan only references net domestic trends. From 2010 to 2016, 71 of 92 counties registered a positive natural increase, and only 14 counties added population through net in-migration. Figure 28 shows the five counties with the most significant net growth in population and the five counties with the most significant net decline in population.
Figure 27. Indiana Population Change by County (2010 - 2016)
Migration trends inform hazard mitigation by highlighting areas of population growth and decline, revealing immigration and emigration patterns, and informing public officials of changes in net adjusted gross income (AGI) as a result of migration.

Figure 29 shows Indiana’s migration patterns between 2010 and 2017 in terms of inbound and outbound domestic migration. Table 6 shows the top 5 states with migration to Indiana and the top 5 states with migration from Indiana.

2.6 Economy

Disasters can significantly disrupt a community’s business operations and overall economy. It is important for key local businesses to have a recovery plan, back-up generator in case of power outage, and disaster insurance. Indiana has a diverse economy with a 2017 gross domestic product (GDP) of $352 billion according to the US Bureau of Economic Analysis, the 16th highest in the nation. Its GDP grew from $280 billion (in current dollars), which represents a 25% increase. Manufacturing represents the largest portion of its GDP, while construction grew the most over that time frame. Figure 30 highlights the industries employing the greatest percentage of workers by county.
Figure 30. Industries Employing Highest Percentage of Workers by County

</table>
Indiana’s 2017 per capita GDP is approximately $48,170 compared to the national average of $55,418 according to the US Bureau of Economic Analysis. According to the US Census Bureau, the poverty rate has been decreasing since 2010. The 2017 poverty rate for Indiana was 13.3%, compared to a national rate of 13.4%. Similarly, according to the US Bureau of Labor Statistics, the state’s unemployment rate has decreased from a high of 11% in January 2010 to 3.3% in June 2018 (compared to a national average of 4%). Unemployed and impoverished populations face special needs in the event of disasters. The following section provides additional information about the unique vulnerabilities of special needs populations.

### 2.7 Special Needs Population

Certain populations require special attention in mitigation planning because they may suffer more severely from the impacts of disasters. It is important to identify these populations and develop mitigation strategies to help them become more disaster-resilient. Although there are numerous types of vulnerable populations, IDHS has identified five significant groups, which include low-income citizens, older adults, non-English-speaking people, people with disabilities, and people without high school diplomas.

Table 8 lists the top 5 counties for each special needs population category. It is important to note that Indiana has a significant Amish population, especially in LaGrange, Elkhart, and Daviess counties. The Amish typically end formal education in the 8th grade and report speaking German, Pennsylvania German, or Dutch at home.

Figure 32 through Figure 36 show the distribution of special needs populations by county.
Non-English speakers are those who speak a language other than English at home. Some of the challenges emergency managers face in helping non-English speakers mitigate disasters include lack of multi-language emergency communications, cultural differences in the way information is interpreted, and mistrust of government services.
Disasters disproportionately affect impoverished populations because they are less likely to have the resources to cope with a disaster’s impacts, which further entrenches them in the poverty cycle. As this figure shows, poverty in Indiana persists in both urban and rural areas.
People with disabilities have physical, sensory, or mental impairments that limit their day-to-day activities. They may be physically challenged by lack of accessibility to services and community assets or cognitively challenged in understanding instructions following the event. Those with sensory disabilities, e.g. blind and hearing impaired, may have difficulty communicating.
As the baby boomer generation continues to age, the percent elderly population will increase. Older adults face many of the same challenges as disabled people including lack of transportation and physical or mental impairments. Additionally, many older adults may require medication or specialized healthcare.
The relationship between education and disaster vulnerability is not well understood. However, education is often associated with both income and poverty. Those with higher education are more likely to have higher incomes and more resources upon which to rely in the event of a disaster.
2.8 Land Use

Community development and transportation demand are primarily driven by population growth, urban and economic development, location of utilities, and land use. The Indiana Department of Transportation (INDOT) is responsible for the development and maintenance of Indiana’s roadway system, which includes US routes and state routes and the overpasses and ramps for these roadways. The other roadways are regulated by local jurisdictions. In total, INDOT maintains 11,000 centerline miles of the state’s 95,701 roadway miles, and over 6,000 bridges (Indiana Department of Transportation, 2013).

Increased urban development occurs as communities develop new residences and businesses to accommodate a growing population. The distribution of projected population growth is heaviest in the urban fringe areas of metropolitan areas as shown in Figure 37. These 14 counties will see the most significant urban development and the highest levels of conversion of rural land to urban uses.

Significant increases in population lead to new development, and it is important to ensure that the new development does not occur in hazard-prone areas. Boone, Hamilton, Hancock, Hendricks, and Johnson counties have been identified for greatest population increase. Fortunately, these counties also have some of the most organized and proactive building codes and stormwater ordinances in the state, and they strictly enforce these codes.

However, many communities with intense development also continue to have localized flash flooding. In Hamilton County, for example, this flash flooding manifests as urban flooding but can also cause small streams and creeks to rapidly rise outside of their banks and floodplains, resulting in damage to infrastructure and uninsured homes and businesses. The storm of June 2008 demonstrated this, and many communities saw devastating floods along smaller creeks and record levels along larger rivers. Some even reached levels beyond the Great Flood of 1913.

Agriculture is also a significant component of Indiana’s existing and future land use. The Indiana Land Resources Council helps local and state decision-makers with land use tools and policies. Part of its mission is to evaluate how Indiana counties can minimize conflicting land uses and ensure that agriculture remains a strong component of the state’s economy. Figure 38 shows the state’s crop and land cover as of 2012.

Land ownership affects how communities can implement mitigation policies and projects. For example, in recent years, the availability for private land for new development has begun to decrease. There is also a small portion of northern Indiana (LaGrange County) designated as tribal land. Figure 39 shows distribution of ownership of significant natural land areas.
Figure 37. Future Population Growth (2015-2050)
Figure 38. Indiana Crop and Land Cover
Figure 39. Ownership of Significant Natural Lands
3 Planning Process

3.1 Plan Update Procedure

The IDHS Mitigation Section is the lead agency responsible for coordinating the State Hazard Mitigation Plan. The State Hazard Mitigation Plan is intended to facilitate mitigation activities throughout the state across the boundaries of federal, state, and local governments and private and nonprofit institutions. To achieve this goal, IDHS collaborated with The Polis Center of Indiana University-Purdue University Indianapolis (IUPUI), multiple state agencies, and the Indiana Silver Jackets Risk Reduction Task Force.

The Polis Center has worked with IDHS since 2003 to develop and update Multi-Hazard Mitigation Plans (MHMP) for 77 of Indiana’s 92 counties. Polis also has been involved in Indiana’s Risk MAP activities in conjunction with IDNR. Risk MAP projects are described in more detail in Section 6.1.3.1 of this plan.

The Indiana Silver Jackets is a multi-agency charter that includes representatives from federal, state, local agencies, higher educational facilities, and regional professional organizations who collaborate to share information and leverage resources to develop sustainable solutions to natural hazard issues.

INDIANA BEST PRACTICE

The Indiana chapter of Silver Jackets is very active in risk-reduction and resiliency projects throughout the state. Since 2007, the Indiana Silver Jackets has successfully completed projects in dam safety, fluvial erosion mitigation, levee identification and mapping, flood risk education and outreach, and much more.

The partnership between IDHS, Polis, and the Indiana Silver Jackets has resulted in a contributing planning team of agencies and subject matter experts as listed in Table 9. These planning team members provided essential input by reviewing drafts of the plan, contributing data to the risk assessment, providing updates on existing and ongoing mitigation activities, and developing new mitigation strategies.

IDHS coordinated with other agencies in a series of meetings during this planning process. Attendance records and meeting minutes for each are available in Appendix A. The core team of IDHS and Polis staff, met on a weekly basis from October 2018 through April 2019. The following meetings included additional staff focused on specific needs:

- **Climate Discussion Meeting (October 31, 2018):** IDHS and Polis staff met with a number of climate specialists from the National Oceanic and Atmospheric Administration (NOAA), the National Weather Service (NWS), IDNR, Purdue University, and the University of Illinois to discuss information related to climate and, in particular, to climate change.

- **Natural Resources Meeting (November 14, 2018 – morning):** IDHS and Polis staff met with IDNR representatives to review datasets that would be relevant for inclusion in the state plan, such as locations of dams, low head dams, bridges, landslides, flood, wetlands, levees, etc.

- **Earthquake Meeting (November 14, 2018 – afternoon):** IDHS and Polis staff met with Indiana University and Indiana University-Purdue University Indianapolis professors to discuss datasets and information related to earthquakes in Indiana.

- **Transportation Meeting (January 7, 2019):** IDHS and Polis staff met with INDOT representatives to review datasets that would be relevant for inclusion in the state plan, such as known landslides, underground coal mines, hazardous materials transportation, maintenance of right-of-ways, and stream gauges.

In addition, the Planning Team wishes to acknowledge the informal guidance and advice provided by members of the Indiana Silver Jackets during their monthly meetings that occurred throughout the planning process.
On March 1, 2019, IDHS issued a press release informing the public that a draft version of the plan would be posted on IDHS’s website and a public meeting would be held at the Indiana Government Center on March 14, 2019. This information was also sent through its GovDelivery Communications Cloud, an email-based communications tool used to distribute notices and press releases. Press releases are distributed to a compiled list of 387 reporters and news outlets throughout the state of Indiana, as well as to another 203 individuals that have requested to receive updates from the office of Public Affairs.

On March 8, 2019, IDHS issued a press release informing the public that a draft version of the plan was made available on its website along with an online survey allowing the public to provide comments on the plan. This press release also utilized the GovDelivery service.

On March 14, 2019, IDHS hosted morning and afternoon meetings at the Indiana Government Center in downtown Indianapolis. IDHS gave a brief overview of the draft plan and sought feedback from the public. All emergency management agency directors within the state were invited.

3.2 Plan Implementation

The Indiana State Hazard Mitigation Officer (SHMO) is responsible for the maintenance and implementation of this plan. The SHMO is also responsible for monitoring the funding and implementation of mitigation strategies in the state administered by the Indiana Department of Homeland Security Mitigation Section.

The SHMO will implement the SHMP through the coordinated efforts of IDHS, various state/federal agencies and the Indiana Silver Jackets (ISJ). Few states have a Silver Jackets chapter as engaged and active as Indiana’s chapter is. The group meets monthly to discuss recent and current mitigation projects and share resources to undertake new activities. The initial focus of the ISJ was addressing statewide flooding concerns. As the ISJ team has evolved and risk exposure has changed, it has begun to take an all hazards approach to risk reduction, focusing on all natural hazards.

The 2019 SHMP defines and prioritizes specific projects and vulnerable communities, it will serve as a guide to the Silver Jackets to determine the highest priority mitigation projects, the best suited agencies to lead those projects, and potential sources of funding. As projects begin, the State Hazard Mitigation Officer will be responsible for coordinating the continued development of the SHMP, finding non-traditional mitigation funding and opportunities for public involvement. Now that IDHS Mitigation Section has sufficient staff, the plan will be reviewed by the SHMO annually or after newly declared disaster events.

3.3 Integration with Other Planning Efforts

The 2019 State Hazard Mitigation Plan integrates with all of the state’s mitigation planning efforts and informs many of the local planning efforts. IDHS Mitigation coordinated with the IDHS Planning Division to understand the breadth of their plan library, how their plans are developed according to existing risks and how the SHMP will be used to integrate all planning activities going forward. The process also considered the planning efforts of a number of other state agencies including the Indiana Department of Transportation, Indiana Department of Natural Resources Incident Emergency Action Plans for high hazard dams in Indiana, and the Office of Community and Rural Affairs Flood Response Plans.
Additionally, the 2019 SHMP integrates with FEMA’s Risk MAP program. Since 2010, IDHS, IDNR, Polis Center and FEMA contractors have partnered with local governments to complete 12 Discovery projects (one additional Discovery project is slated to be completed in 2019). For each Risk MAP initiative, IDHS reviews with participating counties their local mitigation plans and assists them in updating existing strategies and/or offering technical support to develop additional mitigation strategies. This collaborative effort helps local governments take a more holistic approach to planning.

In 2016, IDHS completed a statewide hazard/treat identification and risk assessment. This assessment utilized a modified version of the Calculated Priority Risk Index (CPRI). The HIRA lists the following natural hazards as High or Moderate risk:

- High hazard dam
- Flash flood
- Tornado (EF0-EF5)
- Severe thunderstorm
- Earthquake
- Major levee failure
- Major flood
- Wildfire
- Derecho
- Ice storms
- Drought
- Extreme temperatures

For this update, each hazard was evaluated by a team of subject matter experts who reviewed historical occurrences, mitigation efforts, and known vulnerabilities. Each county Emergency Management Agency was strongly encouraged to complete a county based HIRA using the WebEOC HIRA calculator. Please see Appendix B – 2016 County HIRA for additional details.

### 3.4 Plan Adoption

The Indiana State Hazard Mitigation Plan meets the minimum requirements of Section 409 of the Robert T. Stafford Disaster Relief and Emergency Assistance Act of 1988 (Public Law 93–288 as amended). Additionally, this plan meets the minimum planning requirements under 44 Code of Federal Regulations, Part 78 (Flood Mitigation Assistance).

It is intended that this plan also meet the requirements of the Disaster Mitigation Act of 2000, Section 322. Section 322 requires that states, as a condition of receiving federal disaster mitigation funds, have a mitigation plan in place that describes the planning process for identifying hazards and risks and vulnerabilities. This plan also must identify and prioritize mitigation actions, encourage the development of local mitigation, and provide technical support for these efforts. In addition, the act requires local and tribal governments to have mitigation plans.

Development and implementation of this plan will be carried out in accordance with state regulations and statutes, as well as conform to federal and state laws/statutes that apply when considering intentional, criminal, or unintentional technological and human incidents.
IDHS is responsible for the coordination, preparation, and continuous updating of the SHMP and will ensure that the plan is consistent with federal, county, and municipal plans.

The 2019 State Hazard Mitigation Plan was adopted by the State of Indiana under the executive powers of the governor and approved by FEMA’s Mitigation Division on April 23, 2019.
The goal of mitigation is to build disaster-resistant communities by reducing the impacts of future disasters and lessening the amount of public and private funds spent to assist with disaster recovery. Mitigation actions and projects should be based on a well-constructed risk assessment and should be an ongoing process, adapting over time to accommodate the needs of local communities and the state.

The 2014 SHMP included comprehensive mitigation strategies for each of the identified risks. Due to the lengthy list of strategies identified, IDHS Mitigation was not able to implement all of these strategies. 2014 strategies were carried forward and new strategies collected from planning team members and the Survey Monkey results in Section 9 were added. The 2014 strategies with significant progress made are summarized below.
<table>
<thead>
<tr>
<th>Priority</th>
<th>Goal</th>

<th>Strategy</th>
<th>Section</th>
<th>Strategy Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>High</td>
<td>Integrate Indiana’s mitigation policies and programs to maximize efficiency and leverage funding.</td>
<td>Ensure better coordination of federal, state, and local mitigation activities.</td>
<td>Engage regularly with Congressional and Legislative officials, and especially Congresswoman Susan Brooks, to provide status of state and local mitigation activities</td>
<td>Flood</td>
<td>IDHS and IDNR are in constant contact with elected officials in normal business operations and during emergency events.</td>
</tr>
<tr>
<td>High</td>
<td>Integrate Indiana’s mitigation policies and programs to maximize efficiency and leverage funding.</td>
<td>Identify new partners to collaborate on the state hazard mitigation planning team.</td>
<td>Invite representatives from the social sciences to join the Silver Jackets to better engage local universities to participate in mitigation planning</td>
<td>Flood</td>
<td>IDHS continues to invite partners to join the ISJ Risk Reduction task force. Since the last plan, several agencies have joined the ISJ including but not limited to IHCDA, Purdue Climate Center and the Center for Earth and Environmental Science. The goal for 2109 is to add Department of Energy and the Environmental Protection Agency representatives.</td>
</tr>
<tr>
<td>High</td>
<td>Promote research education, and outreach to expand Indiana’s knowledge about disasters and their impacts.</td>
<td>Review and update existing, or create new, community plans, maps, and ordinances.</td>
<td>Collaborate with Silver Jackets to determine a sustainable funding source for continued collection of LiDAR data</td>
<td>Flood</td>
<td>IDNR continues to work with their funding sources. Mapping progress continues and the goal is to have the state completely mapped by 2020.</td>
</tr>
<tr>
<td>High</td>
<td>Lessen the impacts of disasters to new and existing infrastructure, residents, and responders.</td>
<td>Support compliance with the NFIP.</td>
<td>Use new LiDAR data and ortho products to compile a comprehensive database of building footprints, which will help to promote flood insurance</td>
<td>Flood</td>
<td>INDR continues to work on updating flood maps with new LiDAR data through both the RiskMap efforts and the State Best Available data project.</td>
</tr>
<tr>
<td>High</td>
<td>Promote research education, and outreach to expand Indiana’s knowledge</td>
<td>Conduct new studies/research to profile hazards and promote mitigation.</td>
<td>Conduct research on the social vulnerabilities associated with these hazards</td>
<td>Flood</td>
<td>IUPUI continues to update and share SAVI data on social vulnerabilities. IDHS is partnering with IUPUI to share this information with all aspects of IDHS activities.</td>

## 5 Risk Assessment Overview

### 5.1 Purpose

The goal of mitigation is to reduce the future impacts of a hazard including loss of life, property damage, disruption to local and regional economic activity, and the expenditure of public and private funds for recovery. Sound mitigation must be based on sound risk assessment. A risk assessment involves quantifying the potential losses resulting from a disaster by assessing the vulnerability of buildings, infrastructure, and people. It considers historical data but must be sensitive to emerging trends in climate and weather events in order to adapt mitigation activities accordingly and remain cost effective.

This assessment identifies the characteristics and potential consequences of a disaster, how much of the community could be affected by a disaster, and the impact on community assets.

### 5.2 Indiana’s Disaster History

In the past decade (2008 – 2017), Indiana has had 8 federally-declared disasters and 7 state-declared disasters.

* The State Disaster Relief Fund did not have any funds available at that time.

**Most Recent Disaster (DR-4363):** From February 14 to March 4, 2018, severe storms and flooding affected northwestern Indiana and counties bordering the Ohio River in the southern part of the state. The federal disaster declaration was issued on May 4, 2018 for 31 counties. Total dollars awarded from public and individual assistance to date are $11,162,555.12.

**Most Expensive and Widespread Disaster (DR-1766):** The June 2008 Midwest flooding significantly impacted central and southwest Indiana. The highest recorded rainfall occurred in
the town of Edinburgh, which received nearly 11 inches in seven hours. Many areas of the state were evacuated, including hospitals, and the flooding caused three deaths. 40 of Indiana’s 92 counties were affected. Total dollars awarded from public and individual assistance are $157,372,084.14.

**Most Expensive State Declaration (13569):** SBA Declaration 13569 is a flood event that occurred in April 2013. The State is still processing awards, so total estimates are not yet confirmed; however, the amount awarded is $859,390 for state IA and $795,338.93 for PA, which already far exceed other state declarations. From April 16 to 19, thunderstorms brought heavy rain to much of Central Indiana, and several areas reported between 4 and 8 inches in just three days. The result was flooding of numerous streams and rivers, some of which reached record levels.

### 5.3  Vulnerability Assessment

This SHMP includes 23 hazards: 9 natural, 6 technological (human-caused, accidental), and 7 human (human-caused, intentional). The hazards are listed in Table 12.

**Table 12. Indiana Hazards Addressed in 2019 SHMP**

**5.3.1  Hazus-MH and other GIS Analysis of Earthquake and Flood Impacts**

For the 2014 SHMP update, the State of Indiana provided parcel and property assessment data for all counties except Crawford and Parke. Potential social and economic impacts from flood and earthquake hazards were quantified using FEMA’s Hazus-MH Risk Assessment tool ([https://www.fema.gov/hazus](https://www.fema.gov/hazus)) and other forms of Geographic Information Systems (GIS) analyses that leveraged this data. As a result, the analysis was able to consider factors such as the cost of building construction (labor and materials), the costs to replace building contents, and the value of building inventory. This process reflected an enhanced approach to analyzing hazards as defined for Hazus-MH. The approach included substitution of selected Hazus-MH provided data with local data to improve the accuracy of the model predictions.

As with the 2014 Plan, the 2019 SHMP update included substitution of selected default data with local data. However, this plan includes additional enhancements that improved on the 2014 update including placing a point on the center of the largest building of each parcel to represent buildings in the parcel instead of locating the point on the centroid of the parcel. This improved building inventory was specifically applied to model flood hazard impacts (see Section 5.5).

The 2019 SHMP update leveraged Hazus-MH version 4.2.1 to generate a combination of site-specific and aggregated loss estimates. Aggregated inventory loss estimates, which for this study included
earthquake building economic and structural resiliency impact analysis, are based upon the assumption that buildings are evenly distributed across the landscape.

Site-specific analysis in this study was based upon loss estimations for individual structures. In Hazus-MH, factors that guide how structures will respond to hazards vary by what is being evaluated. For example, estimates of damage to structures from flooding take into account the depth of water in relation to the structure. It is also important to note that Hazus-MH applies a number of assumptions in its processes. For instance, it is assumed that each structure will fall into a structural class, and structures in each class will respond in a similar fashion to a specific depth of flooding. Site-specific analysis is also based upon a point location rather than a polygon; therefore, the model does not account for factors such as the percentage of a building that is inundated.

It is important to note that Hazus-MH is not intended to be a substitute for detailed engineering studies. Rather, it is intended to serve as a planning aid for communities interested in assessing their risk to selected natural hazards. This documentation does not provide full details on the processes and procedures completed in the development of this project. It is only intended to highlight the major steps that were followed during the project.

5.3.2 Historical

The state conducted historical vulnerability assessments for each hazards hazard. This process included documentation of previous occurrences in the past 50 years and analysis of how likely and how impactful the hazard would be if it occurred today.

As with the 2014 SHMP, the 2019 plan does not include a detailed vulnerability analysis for many of the technological and human hazards due to concerns over publication of sensitive data. These analyses exist in the State of Indiana Threat and Hazard Identification Risk Assessment (THIRA) and the State of Indiana Comprehensive Emergency Plan.

5.4 Hazard Prioritization

In 2018, IDHS conducted a unified State-level THIRA to classify Indiana hazards as high risk, moderate risk, or low risk based on the probability of occurrence and the potential impact of the occurrence. The THIRA results are included in Appendix B. The guidelines used to determine probability and impact ratings are listed in Table 13.

Table 13. Guidelines for Hazard Prioritization

<table>
<thead>
<tr>
<th>PROBABILITY</th>
<th>IMPACT</th>
</tr>
</thead>

</tr>
<tr>
<td></td>
<td>• Loss of public utilities, government, and social services for up to 2 weeks</td>
</tr>
<tr>
<td></td>
<td>• Response operations lasting up to 2 weeks may be required.</td>
</tr>
</tbody>
</table>
The overall hazard risk is determined by multiplying probability and impact. It is important to consider both probability and impact when determining risk. IDHS plotted each hazard on a risk grid according to probability (y-axis) and potential impact (x-axis). Figure 40 represents the state’s overall hazard vulnerabilities.

*Figure 40. Hazards Risk Grid*

5.5 Essential Facilities & State-Owned Facilities

5.5.1 Essential Facilities

For the purpose of this plan, essential facilities are defined as those that are vital to the state in the event of a hazard. These include emergency operations centers, police departments, fire stations, schools, and care facilities.

The essential facility updates were applied to the Hazus-MH model using data from local MHMPs and data from the Indiana Department of Education, Indiana Department of Health, and IDHS. Hazus-MH reports of essential facility losses reflect updated data. A summary of the essential facility updates is included in Table 14.

**INDIANA BEST PRACTICE**

Hazus-MH is a valuable tool for assessing vulnerability in mitigation planning. Since 2003, IDHS and The Polis Center have partnered with local officials to complete over 100 multi-hazard mitigation plans using Hazus Level 2 or Advanced analyses in the risk assessments.

In 2018, Microsoft released 125 million building footprints for the United States that were generated from imagery using machine learning (https://github.com/Microsoft/USBuildingFootprints). This data is licensed through the Open Data Commons Open Database License. The Polis Center extracted the building footprints for the state of Indiana and created point centroids of each building. Each building centroid was then joined spatially to the state’s land parcels provided by the Indiana Geographic Information Office on April 12, 2018 via IndianaMAP. This process provided the parcel identifier for each building and was then linked to the statewide Real Property Tax Assessment Data provided by the Indiana Department of Local Government and Finance (IDLGF) from April 2018, also available via IndianaMAP. Indiana counties annually submit an extract of property appraisal data to the IDLGF that contains detailed building information such as square footage, construction type, year built, foundation type, and building replacement cost. The IDLGF data allows Polis to identify the occupancy class of each building based on the parcel within which it is located. Approximately 1% of the buildings were not located in a parcel and were not included. Table 15 provides the number of parcels and their total improvement value from the IDLGF dataset, organized by occupancy class, along with the number of Bing buildings located within those parcels.

<table>

### 5.6 Change in Development

According to the IDLGF database described above, 156,321 parcels have an effective construction year between and including 2014 and 2019. According to the same database, the appraised value for these parcels totals $17 billion dollars. Table 18 breaks down the parcels by occupancy class while Table 19 breaks their value down by county.

6 Natural Hazards

6.1 Flood

Flooding is a significant natural hazard throughout the US. The type, magnitude, and severity of flooding are functions of the amount and distribution of precipitation over a given area, the rate at which precipitation infiltrates the ground, the geometry of the catchment, and flow dynamics and conditions in and along the river channel. Floods in Indiana can be classified as one of two types: flash floods or riverine floods, both are common in Indiana.

Flash Floods

Flash floods generally occur in the upper parts of drainage basins and are generally characterized by periods of intense rainfall over a short duration. These floods arise with very little warning and often result in locally-intense damage and, sometimes, loss of life due to the high energy of the flowing water. Flood waters can snap trees, topple buildings, and easily move large boulders or other structures. Six inches of rushing water can upend a person, while another 18 inches can carry off a car. Generally, flash floods cause damage over relatively localized areas, but they can be quite severe in the areas in which they occur. Urban flooding is a type of flash flood. Urban flooding involves the overflow of storm drain systems and can be the result of inadequate drainage combined with heavy rainfall or rapid snowmelt. Flash floods can occur at any time of the year in Indiana, but are most common in the spring and summer months.

Riverine Floods

Riverine floods refer to floods on large rivers at locations with large upstream catchments. Riverine floods are typically associated with precipitation events that are of relatively long duration and occur over large areas. Flooding on small tributary streams may be limited, but the contribution of increased runoff may result in a large flood downstream. The lag time between precipitation and time of the flood peak is much longer for riverine floods than for flash floods, generally providing ample warning for people to move to safe locations and, to some extent, secure property against damage. Riverine flooding on the large rivers of Indiana can occur anytime but occur most often during the spring or summer.

Over the past 30 years, communities throughout the state have worked with the IDHS Mitigation Program to apply for and receive FEMA grant funding to voluntarily acquire and demolish over 1,200 flood prone residential properties. The jurisdictions of the City of English, Vigo County, City of Ft. Wayne, Morgan County, City of Franklin, and City of Decatur have each acquired and demolished more than 75 residential properties, and returned the land to natural green space. This type of mitigation will eliminate the flood risk to the participating homeowners and increase the natural flood storage of the area. These properties become deed restricted in perpetuity, to restrict future redevelopment.
6.1.1 Historical Occurrences

From 2008 to 2017, Indiana received 5 federal disaster declarations related to flooding. Individual Assistance (IA) approved for these declarations totaled $104 million and Public Assistance (PA) obligated totaled $144.5 million.

The most recent federal disaster declaration (DR-4363) occurred in early 2018 when severe storms and flooding caused extensive and record flooding along the Yellow, Kankakee, and Iroquois Rivers. The IA and PA for this disaster are not included in the numbers above since they are still being finalized. Figure 41 shows the extent of the early 2018 flooding, the affected parcels, and both their land and improvements values according to the IDLGF database.

### 6.1.2 Vulnerability Assessment

Vulnerability to flooding was determined in three ways: 1) Hazus-MH Level 2 analysis, 2) analysis of community participation in the National Flood Insurance Program (NFIP), and 3) an overview of repetitive and severe repetitive loss properties.

It is important to note that the losses to buildings, particularly essential facilities, extends beyond physical damage. The economic and social impacts associated with loss of governmental, public safety, and health care infrastructure are far more significant for a community. When assessing the cost of building construction, it is important for government agencies to consider these impacts.

#### 6.1.2.1 Hazus-MH Analysis

Hazus-MH generated the flood depth grid for a 100-year return period event and made calculations by clipping the digital elevation model (DEM) to the 100-year Digital Flood Insurance Rate Map (DFIRM) boundary. Hazus-MH then utilized a level 2 user-defined analysis of the state with site-specific building data combined with IDLGF assessor data. More information on the creation of the statewide site-specific building data can be found in Section 5. It is important to remember that Hazus-MH is not a substitute for detailed engineering studies or as a response tool. Rather, it serves as a planning aid for communities interested in assessing their risk to flooding, earthquake, and hurricane-related hazards.

Hazus-MH estimates the 100-year flood would damage 57,377 buildings at a replacement cost of $5.2 billion statewide. IDHS District 5 experienced the most damage to buildings, totaling $1.4 billion in damages with 15,000 buildings affected. Figure 43 shows the loss ratio by county for flood damage. The loss ratio is calculated by dividing the estimated building damages by the total replacement cost.

The total estimated amount of damages to buildings are listed in Table 24 and mapped in Figure 42. Residential structures are by far the most susceptible to damage and comprise 80% of the total buildings.

damaged. They only comprise 48% of the total amount of damage done to buildings. The total number of buildings damaged is summarized in Table 25 and mapped in Figure 44 and Figure 45.

6.1.2.2 Analysis of Essential Facilities

While damage to any building in the event of a flood would be detrimental, essential facilities are of particular concern as they provide services essential the emergency response abilities of the county. For this reason, essential facilities were closely examined in relation to the Special Flood Hazard Area (SFHA) boundary. A total of 161 facilities were mapped as intersecting the SFHA for Indiana. These facilities have been listed, by type, in Table 23 and are mapped in Figure 46 through Figure 50.

<td>77</td>
</tr>
</tbody>
</table>

6.1.2.3 Analysis of State Facilities

INDOT has a total of 224 facilities statewide and IDNR has 780, covering every county in the state. Of those, 6 INDOT and 45 IDNR facilities were mapped as being within the SFHA, thus susceptible to flooding in the event of a 100-year flood. As can be seen in Figure 51, the affected INDOT facilities are mainly located in south central Indiana while the IDNR facilities are spread throughout the state. These damaged facilities would be unable to lend aid in the event of a disaster.

6.1.2.4 Analysis of Newly Developed Properties

As described in Section 5.6, a number of parcels in the state had improvements made to them from 2014 to 2019. Figure 52 displays the locations of the buildings located on these parcels. A total of 1,514 buildings were found to be located in those parcels. Note that some buildings may be missing due to differences in data sources and that this does not necessarily indicate new construction on a property.

Figure 44. Percent Projected Buildings Damaged
Figure 45. Projected Total Buildings Damaged

The map shows the projected total buildings damaged across various districts in Indiana. Each district is color-coded to indicate different ranges of buildings damaged:

- Buildings Damaged Count:
  - ≤100
  - >100 and ≤500
  - >500 and ≤1000
  - >1000 and ≤2500
  - >2500 and ≤5000
  - >5000 and ≤10000
  - >10000 and ≤11000

The map uses different shades of blue to represent these ranges. The legend indicates what each color represents. The districts are labeled, and the map provides a visual representation of the projected damage.

6.1.2.5 National Flood Insurance Program

The NFIP seeks to reduce the impact of flooding on private and public structures by providing affordable insurance for property owners. It is IDHS’s goal to encourage more communities to adopt and enforce floodplain management regulations, which will mitigate the effects of flooding new and improved structures.

Since 1978, the NFIP has paid more than $68 billion in flood insurance claims in the United States, including over $273 million in Indiana.

The NFIP has three major functions that focus on reducing flood risk and the impact of flood disasters:

1. **Flood Hazard Mapping and Risk Analysis**: The NFIP requires reliable information about flood risk, which it obtains through FEMA’s Risk Mapping, Assessment, and Planning (Risk MAP) program. Risk MAP is a multi-year mapping effort designed to meet the FEMA statutory requirement to review flood hazards maps every five years and address flood hazard data updates as funding is available.

2. **Reducing Flood Risk**: Local floodplain managers are encouraged to seek flood-related grants and assistance such as Flood Mitigation Assistance (FMA), Repetitive Flood Claims (RFC), and Severe Repetitive Loss (SRL). By law, FEMA can only provide flood insurance to homeowners of communities that adopt and enforce floodplain management regulation and meet NFIP’s requirements.

3. **Insuring Flood Risk**: Homeowners in communities participating in the NFIP can purchase affordable protection to insure against flood losses.

To help better understand flood risk, the total structures in the SFHA were compared to the total number of policies in the community. This is based on the approximate buildings locations, and therefore should not be used as an absolute comparison. However, this information may be used to target further mitigation through additional engagement with the NFIP. Table 26 displays the insurance policies and total coverage for each county as well as the estimated number of buildings in the SFHA along with total estimated replacement cost. The last two columns represent the approximate percentage of buildings insured and the approximate percentage of exposure. Figure 53 maps the percentage of buildings insured, the total number of estimated buildings in the SFHA divided by the total number of polices in the county. Figure 54 maps the total amount of estimated exposure.

6.1.2.5.1 Community Rating System (CRS)

The NFIP’s Community Rating System (CRS) was implemented in 1990 and recognizes and encourages community floodplain management activities that exceed the minimum NFIP standards. Any community that is in full compliance with the NFIP’s minimum floodplain management requirements may apply to join CRS. Nearly 3.6 million policyholders in 1,444 communities participate in the CRS by implementing local mitigation, floodplain management, and outreach activities that exceed the minimum NFIP requirements.

Under the CRS, flood insurance premium rates are discounted to reward community actions that meet the three goals of the CRS, which are: (1) reduce flood damage to insurable property; (2) strengthen and support the insurance aspects of the NFIP; and (3) encourage a comprehensive approach to floodplain management. Although CRS communities represent only 5 percent of the over 22,000 communities participating in the NFIP, more than 69 percent of all flood insurance policies are written in CRS communities.

Besides the benefit of reduced insurance rates, CRS floodplain management activities enhance public safety, reduce damages to property and public infrastructure, avoid economic disruption and losses, reduce human suffering, and protect the environment. Technical assistance on designing and implementing some activities is available at no charge. Participating in the CRS provides an incentive to maintaining and improving a community’s floodplain management program over the years. Indiana has a total of 34 communities and counties participating in the CRS. These are listed in Table 28.

In Indiana CRS communities can get higher credit for Activity 340 Hazard Disclosure, Activity 410 Mapping and Regulations for the state having more restrictive floodway regulations, Activity 430 Higher Standards for having a 2’ freeboard and Activity 610 Dams if a community has a state-regulated high hazard dam that would affect them.

The cities of Fort Wayne and Noblesville were some of Indiana’s earliest participants in the CRS along with Hamilton County. Since the 2014 plan, 15 communities and counties joined the CRS, furthering
Indiana’s commitment to upholding the NFIP. Those communities are Lake, Huntington & Wells counties, the cities of Bluffton and Huntington, and the towns of Dyer, Merrillville, Andrews, Ossian, Roanoke, Vera Cruz, Warren and Zanesville.

6.1.2.5.2 IDNR “Best Available” Floodplain layer

For many years, the IDNR Division of Water has assisted Indiana communities in determining base flood elevations (BFEs) and floodway limits for streams that did not have detailed floodplain information shown on their FIRMs. Typically, this included asking requestors for survey data, then using that data to run hydrology and hydraulic models to determine floodplain limits on a case-by-case basis.
Because this process took months to complete, both from obtaining the survey data and the modeling by the Division of Water, floodplain management activities suffered due to the time lag. However, with the advent of detailed GIS data, namely LiDAR elevation data, many of the traditional barriers to completing high-level floodplain information have been removed.

The Division of Water has completed a dataset for the state that incorporates the detailed level-floodplain data included in the FEMA FIRMs and enhanced it with a lower-level, but still quality, floodplain data for the majority of all streams in Indiana. This dataset is known as the “best available” floodplain layer, due to the phrasing of the standard local floodplain ordinance in Indiana, which requires the use of “best available” data to make sound floodplain management decisions when the needed information is not available on the FEMA FIRM.

The dataset features flood elevations for five annual chance flood return periods (10%, 4%, 2%, 1% and 0.2%), as well as floodplain and floodway limits for more than 18,000 miles of stream that previously only had Zone A or Zone X designations on the FIRMs. Along with the 4,000 miles of stream published on the FIRMs with elevation and floodway data, this dataset provides floodplain data for more than 22,000 miles of stream in Indiana, covering every major waterway in the state, along with many critical tributaries.

In February and March 2019, IDNR Division of Water hosted multiple webinars to introduce these data to community planners, engineers, surveyors, realtors, and other stakeholders.

6.1.2.6 Repetitive & Severe Repetitive Loss

FEMA provides annual funding through the National Flood Insurance Fund (NFIF) to reduce the risk of flood damage to existing buildings and infrastructure. The Flood Mitigation Assistance (FMA) program, created as part of the National Flood Insurance Reform Act of 1994, aims to reduce or eliminate claims under the National Flood Insurance Program. FMA funding is available through the National Flood Insurance Fund (NFIF) for flood hazard mitigation projects as well as plan development. FMA includes the RL and SRL programs.

FEMA defines a repetitive loss structure as a structure covered by a contract of flood insurance issued under the NFIP, which has suffered flood loss damage on two occasions during a 10-year period that ends on the date of the second loss, in which the cost to repair the flood damage is 25% of the market value of the structure at the time of each flood loss.

A severe repetitive loss property is defined as a residential property covered under an NFIP flood insurance policy and:

A) Has at least four NFIP claim payments over $5,000 each with a cumulative payment amount that exceeds $20,000.

OR

B) For which at least two separate claims payments (building payments only) have been made with the cumulative amount of the building portion exceeding the market value of the building.
For both A and B, at least two of the claims must have occurred within any 10-year period and must be greater than 10 days apart.

Table 31 lists all repetitive (RL) and severe repetitive loss (SRL) information for the state of Indiana, grouped by county. Statewide, there are 1,582 properties reported as a repetitive loss, with the total number of losses submitted recorded at 3,919. Of those losses reported, 1,387 were single-family properties, the remaining 195 were a mix of residential and non-residential properties.

Statewide, there are 240 properties reported as a severe repetitive loss, with the total number of losses submitted recorded at 1,258. Of those losses reported, 217 were single-family properties; the remaining 23 were a mix of residential and non-residential properties.

Table 29 and Table 30 list the top five communities with the most repetitive & severe repetitive loss properties reported.

6.1.3 Risk Mapping, Assessment, and Planning

The vision for Risk MAP is to deliver quality data that increases public awareness and leads to action that reduces risk to life and property. Since the launch of the program in 2010, Indiana has been actively involved in Risk MAP’s various phases, and IDHS and Polis have incorporated key recommendations and mitigation strategies into the flood vulnerability assessment of this plan.

6.1.3.1 Indiana RiskMAP Activity

Discovery: The Discovery phase helps communities better understand local flood risk and mitigation efforts and encourages watershed-wide discussions about increasing resilience to flooding. Figure 55 identifies the watersheds in Indiana that have completed or are currently undergoing Discovery stakeholder meetings and developed final Discovery reports. IDNR, IDHS, and Polis led or participated in each of the Discovery initiatives.

Non-Regulatory Products: Indiana has been heavily involved in developing Risk MAP regulatory products for all 92 counties in the state. This includes updating FIRMs and FIS that focus on the probability of floods and describe where and how often flooding may occur. Of the 92 counties in Indiana, 89 have had their flood maps modernized to digital form. The three counties that do not have completed digital form are Sullivan, Knox and Daviess Counties.

The following lists some of the non-regulatory RiskMAP products the state of Indiana has completed:

- City of Tipton Flood Resilience Plan (Christopher B. Burke Engineering, Ltd.)
- North Vernon Tier 1 Country Squire Dam Inundation Mapping (IDNR, Polis)
- Logansport Tier 1 Goose Creek Report (IDNR, Polis)
- Owen County Transportation Vulnerability Analysis (IDNR, Polis)
- White Lick Creek System Assessment (Christopher B. Burke Engineering, Ltd.; Indiana University-Purdue University Indianapolis Center for Earth and Environmental Sciences)
- Brown County Dam EAPs (IDNR, Polis)
- City of Washington Hawkins Creek Analysis (IDNR, Polis)
- City of Winchester, Sugar Creek and Salt Creek Analysis (IDNR, Polis)
- Town of Ellettsville, Jacks Defeat Creek Analysis (IDNR, Polis)
Figure 55. RiskMAP Discovery Projects
The cities of Lebanon & Crawfordsville are both in the process of RiskMAP projects that hope to be completed in the near future. The City of Lebanon is working to create a flood resilience plan while the City of Crawfordsville is working on a study of the Sugar Creek Erosion issue.

In addition, mapping updates have been scheduled to counties within the following watersheds; Sugar Creek, Middle Wabash Busseron, Lower Wabash, Upper Wabash, and Lower White.

**Depth Grid Development:** Indiana has worked to create depth grids statewide and has made considerable progress. Below is a list of county and/or community depth grid projects along with a brief description of the project.

- **City of Noblesville, IN**
  - Depth grids created for White River near the wastewater treatment plant.

- **Harrison County, IN**
  - Depth grids created along the Ohio River.

- **City of Salem, IN**
  - Depth grids created for three areas identified by City.
  - These areas include portions of Highland Creek, Brock Creek and West Fork Blue River.

- **Floyd County, IN**
  - Depth grids created for five areas identified by County.
  - These areas include portions of Indian Creek, Yellow Fork, Georgetown Creek, Little Indian Creek, and Fall Run.

- **Towns of French Lick and West Baden, IN**
  - Depth grids created for two areas identified by the Towns.
  - These areas include portions of French Lick Creek within the town limits of French Lick and West Baden and Lost River to the north of the town limits of West Baden.

- **Washington County, IN**
  - Depth grids created for four areas identified by County.
  - These areas include portions of East Fork White River, Muscatatuck River, West Fork Blue River, South Fork Blue River and an area near West Washington School Road.

- **Jackson County, IN**
  - Depth grids created for five areas within the county. These areas were identified based on high populated areas within the 1-percent-annual-chance floodplain.
  - These areas include portions of Medora Creek and South Branch Medora Creek in the Town of Medora. Along a portion of East Fork White River northwest of the Town of Brownstown, along a portion of East Fork White River northwest of the City of Seymour, along a portion of Von Fange Ditch in the City of Seymour, and along a portion of Grassy Fork near intersection of County Road 600 and State Road 39.

- **City of Tipton, IN**
  - Depth grids were created as part of a demonstration project for the City of Tipton. These were part of a suite of Non Regulatory products including Changes Since Last Firm and Chance of Flooding Over 30 Years.
  - These were created for a portion of Big Cicero Creek.
6.1.4 Indiana Stream Gauges

The USGS, in cooperation with many state agencies and local utility and surveyor offices, helps maintain stream gauges, which provide the capability to obtain estimates of the amount of water flowing in streams and rivers. Water managers, emergency responders, utilities, environmental agencies, universities, consulting firms, and recreational enthusiasts use data from the stream gauge network to understand the flow of water in their area. IDNR and the Indiana Department of Environmental Management (IDEM) use the stream gauge data for water quantity and quality measurements. Local public safety officials use the data at these sites, along with the resources from the NWS, to determine emergency management needs during periods of heavy rainfall. Stream gauges for the state of Indiana have been mapped in Figure 56.

6.1.5 Probability of Future Occurrences

The probability of future occurrences of flooding—expressed in terms of frequency—is the likelihood that a specific event will happen. The Hazus analysis in this chapter identified the current facilities that are at risk for a 1%-annual-chance flood, based on the NFIP maps and studies that use the 1%-annual-chance floodplain area (area inundated during a 100-year flood). Due to the unpredictability of this hazard, both rural and urban areas in Indiana are at risk. Controlling floodplain development is an important step to reducing food-related damages. Areas with recent development within the county may be more vulnerable to drainage issues, which could induce flash flooding as well as exacerbating flooding problems. As was covered in Sections 2.2.2.2 and 2.2.2.3 of this plan, current climate research indicates that Indiana will begin to experience wetter winters and springs and will continue to experience extreme rainfall events. These increase the chance of extreme flooding events as well as placing extra strain on combined sewer systems, which often overflow in the event of flooding. An increase in frequency and intensity of flooding events in the years to come means an even greater strain on flood control systems statewide.
Figure 56. Indiana Active Stream Gauges
6.2 Severe Weather

The World Meteorological Organization defines severe weather as any dangerous meteorological phenomena with the potential to cause damage, serious social disruption, or loss of human life. For Indiana, those include thunderstorms, tornadoes, high winds, hail, and excessive precipitation. Floods are covered in Section 6.1 and winter storms are covered in Section 6.6. This section focuses on thunderstorms and related severe weather such as tornadoes, damaging winds, and hail.

Severe weather can occur during any month of the year and at any time during the day or night. Their unpredictability and potentially deadly impact make them one of Indiana’s most dangerous hazards. Thunderstorm wind is the most common storm event type in Indiana (see Table 4).

Thunderstorms

According to NOAA’s National Severe Storms Laboratory (NSSL), a thunderstorm is a rain shower that includes lightning. A severe thunderstorm is a thunderstorm that has one or more of the following: hail one inch or greater, winds gusting in excess of 50 knots (57.5 mph), or a tornado.

There are about 100,000 thunderstorms each year in the United States; about 10% of them are severe.

Tornadoes

Tornadoes are defined as violently rotating columns of air (funnel clouds) extending from thunderstorms to the ground. Once the funnel cloud touches the ground, it becomes a tornado.

There are about 1,000 tornadoes each year in the United States. Tornadoes are classified according to the Enhanced Fujita intensity scale shown in Table 32.

<td>100-315 miles</td>
<td>Foundations swept clean, automobiles become missiles and thrown for 100 yards or more, steel-reinforced concrete structures badly damaged.</td>
</tr>
</tbody>
</table>

Damaging Winds

Damaging winds are often called “straight-line” winds resulting from strong thunderstorms in order to differentiate the damage they cause from tornado damage. Damaging winds are classified as those exceeding 50-60 mph.
A Derecho is a widespread, long-living, and fast moving windstorm, associated with bands of showers or thunderstorms. Although a derecho can produce destruction similar to that of a tornado, the damage typically occurs in one direction along a relatively straight path. By definition, if the swath of wind damage extends for more than 250 miles, includes wind gusts of at least 58 mph along most of its length, and includes multiple instances of wind gusts of at least 75 mph or more, then the event may be classified as a derecho. A derecho is known for its distinctive bow signature, and the fact that they can occur over a period of several hours.

Derechos are most common during the summer months, making those involved in outdoor activities especially at risk. Another reason that those outdoors are vulnerable to derechos is the rapid movement of the parent convective system. Typically, derecho producing storm systems move at speeds of 50 mph or greater, with a few clocked at greater than 70 mph.

**Hail**

Hail is a form of precipitation that occurs when updrafts in thunderstorms carry raindrops upward into extremely cold areas of the atmosphere where they freeze into balls of ice. Hail can damage aircraft, homes and cars, and can be deadly to livestock and people.

**Lightning**

Lightning is a giant spark of electricity in the atmosphere between clouds, the air, or the ground. Thunder, the sound wave caused by lightning, can be heard up to 25 miles away from the lightning discharge.

### 6.2.1 Historical Occurrences

On June 30-July 1, 2014, a pair of derechos swept through the Mississippi Valley and Great Lakes Region producing a swath of damage. NOAA called it an unusual “One-Two Punch”. The most intense activity was over northern Indiana, northern Illinois, Nebraska, and Iowa. The derechos produced 300 reports of severe weather, 24 tornadoes, wind gusts of over 75 mph, and two-inch diameter hail. Throughout Indiana, roofs were damaged, trees were uprooted, and power lines fell. A tree that fell onto a mobile home in Winona Lake, IN killed a teenager inside the home. In Big Long Lake, IN, a man was killed when a large tree fell through the roof of his house. High winds caused the partial collapse of a roof and wall at a school in LaGrange County, IN.
Figure 57. July 2014 Derechos

Figure 58 illustrates historical tornado paths from 1950 to 2017 as reported to NOAA.
Figure 58. Historic Tornado Paths
On Palm Sunday, April 11, 1965, Indiana was one of six Midwest states hit by an outbreak of deadly tornadoes. In total, 47 tornadoes killed 271 people and injured over 1,500. According to the NWS, this is the deadliest tornado outbreak in Indiana history, with 145 killed and over 1,200 injured. The twin tornadoes that struck Dunlap, IN (Figure 59) killed 45 people, 33 of which were in a mobile home community. Other northern Indiana communities that were affected by this outbreak include South Bend, Goshen, and Elkhart. In central Indiana, a tornado destroyed much of the town of Russiaville, and caused severe damage on the south side of Kokomo. Other central Indiana communities affected include Greentown and Marion. In all, there were eight F4 and two F3 tornadoes that struck the state that day (see Figure 59 and Figure 60).

*Figure 59. Palm Sunday, April 11, 1965 Twin Tornadoes in Dunlap*

*Source: Paul Huffman for National Oceanic and Atmospheric Administration [Public domain], via Wikimedia Commons*
On April 3-4, 1974, the United States experienced the largest tornado outbreak in the nation’s history at that time. The “Super Outbreak” consisted of 148 tornadoes that swept across 13 states (Figure 61). According to the NWS, this was one of the largest tornado outbreaks in Indiana history, with 21 tornadoes striking 38 counties, killing 47 and injuring nearly 900. One tornado was on the ground for 121 miles and severely damaged the communities of Monticello, Rochester, and Ligonier. In Monticello, three schools were destroyed, and statewide, 24 schools were damaged or destroyed. Of the 21 tornadoes to strike the state during this outbreak, seven were classified at F4 strength, and two were rated as F5. This is the most recent occurrence of an F/EF5 tornado in Indiana.
Figure 61. April 3-4, 1974 Super Outbreak

Source: From the National Weather Service, Courtesy of Ted Fujita
From January 1, 2013 to October 31, 2018, there have been 2,308 high wind, lightning, hail, and thunderstorm wind events reported to NCDC. These events resulted in 9 deaths, 38 injuries, and $72 million in damages. Table 33 lists the NCDC reports by county and district.

6.2.2 Vulnerability Assessment

Because the threat of severe weather is equally distributed across the state (see Figure 62), all communities and infrastructure are vulnerable. The types of infrastructure impacted could include roadways, utility lines, railroads, bridges, and more. Physical impacts may include structural failure, damaging debris (trees or limbs), roofs blown off or windows broken by hail or high winds, impassable bridges and roadways, fires caused by lightning, and lost building functionality.
The vulnerability assessment for tornadoes is similar to that of severe thunderstorms and often results in the same types of physical impacts, though usually more severe. Based on reported damages from tornadoes, urbanized and industrial areas face the greatest vulnerability because of their concentration of buildings, population, and lifeline utilities. Rural communities also face the potential for significant economic impact from loss of crops, livestock, and storage facilities. Because the economy in rural counties is less diversified than in urban areas, the impacts of a tornado may destroy the economic livelihood of a majority of the county’s population.

Figure 62. Wind Zones in the United States (FEMA)

6.2.2.1 GIS Tornado Analysis

The Polis Center modeled two tornado scenarios, the November 6, 2005 EF3 that crossed through Vanderburgh and Warrick Counties and the 2012 EF4 event that crossed through Washington, Clark and Jefferson Counties.

Within any given tornado, there are degrees of damage. The most intense damage occurs within the center of the path with decreasing amounts of damage away from the center. Table 35 describes the damage zones of EF3 and EF4 tornadoes used during the analysis.
6.2.2.1.1 Evansville Tornado

The November 6, 2005 EF3 tornado was tracked for 41 miles from Henderson County, KY through Vanderburgh, Warrick and into Spencer County, IN. According the NCDC database, it was the deadliest tornado in Indiana since April 1974. The tornado entered Vanderburgh county near Ellis Park horse racing facility moving east-northeast at close to 60 mph staying south of Evansville city limits. The path crossed through a mobile home park of about 350 homes. One hundred mobile homes were destroyed and another 125 were damaged. The tornado then moved into Warrick County just south of Interstate 164 at the Angel Mounds State Historic Site. It crossed the entire county in less than 20 minutes. The tornado reached its peak intensity in Warrick County causing winds to reach about 200 mph.

The tornado caused $80 million in property damage, 24 deaths and injured 230. Figure 63 shows the path of the tornado.

Beginning in 2015, IDHS applied for and received a FEMA Pre-Disaster Mitigation grant to provide a rebate for homeowners to install/construct a residential safe room at their residence. To date, IDHS has provided funding for up to 40 homeowners to complete installation/construction of these life-saving shelters. The first FEMA grant funded residential safe room was installed underground in the backyard of a home in Evansville, IN, in January 2018. Due to the high interest in this program, IDHS will continue to apply for additional grant funding for residential safe rooms in the years to come. For more information on Indiana’s Residential Safe Room Program, visit the program website at: https://www.in.gov/dhs/4140.htm.
The GIS analysis of the historic Evansville tornado reported damage to eight essential facilities, listed in Table 37 and shown in the map in Figure 65. No INDOT or IDNR facilities were found to be in the path of the tornado. This model predicts estimated damages based on the best available data. The results may not match those actually incurred in 2005.

6.2.2.1.2 Henryville Tornado

The March 2, 2012 EF4 tornado carved a 49-mile path through Indiana’s Washington, Clark, and Jefferson counties and into Kentucky. The tornado touched down first in Washington County just south of Fredericksburg. The tornado path widened and intensified after crossing farmland, toppling a high-tension metal power structure. After passing south of New Pekin, a large well-constructed factory building was cleared to its foundation slab, numerous anchoring bolts having been bent or stripped. The tornado traveled 17 miles in Washington County, felling thousands of trees and destroying scores of buildings. The tornado caused $2 million in property damages and five deaths before moving into Clark County.
The tornado moved into Clark County with a path width of one-third of a mile destroying or severely damaging numerous homes and businesses in its path across the county. As the tornado crossed Interstate 65, several people were trapped within damaged vehicles, resulting in the closure of the highway for several hours. The Henryville Junior-Senior High School sustained severe damage, the cafeteria was completely destroyed and six automobiles were piled up along the south side of the school. A Civil Air Patrol Flight revealed extensive ground scouring across several fields east of Marysville indicating a multiple vortex tornado. The tornado caused one death in Clark County and property damages were estimated at $55 million.

The tornado continued into Jefferson County, destroying several mobile homes, severely damaging several frame houses, power lines and felling many trees. As the tornado moved south of Chelsea, it destroyed several well-built brick homes with anchor bolts attached to steel plates and a concrete foundation. One home was lifted and slid 65 yards off its foundation while remaining essentially intact. Wind speeds were estimated at around 170 mph with a damage width of one quarter of a mile. The tornado caused 4 deaths and an estimated $750,000 in property damages before exiting Jefferson County and moving over the Ohio River. Figure 66 shows the path of the tornado.

Figure 66. Henryville Tornado Path and Projected Building Losses

Within any given tornado, there are degrees of damage. The most intense damage occurs within the center of the path with decreasing amounts of damage away from the center. Using data provided by the NWS for the boundary of the 2012 tornado path, the Polis Center used a GIS model to predict building inventory losses.

According to the analysis, the tornado damaged 510 buildings at a total replacement cost of $59.4 million. The results by occupancy are listed in Table 38, and Figure 67 shows the building losses by varying degrees of damage.
Note: In 2012, there were two tornadoes that ran through the same relative area of Southern Indiana. The first was an EF4 and the second an EF3. This model predicts estimated damages based on the best available data for the EF4 event. The results may not match those actually incurred in 2012.

Figure 68. Projected Henryville Tornado Essential Facilities Damage

In 2014, IDHS worked with Salem Community Schools in Washington County, IN, to apply for and receive a FEMA Pre-Disaster Mitigation grant to build a community safe room at Bradie Shrum Elementary School, in Salem, IN. The safe room, completed in May 2018, consists of four classrooms and a multi-purpose room that can be used to protect the entire student body of the school, along with staff and guests, during severe weather events. Additional schools and not-for-profit organizations have worked with IDHS to apply for FEMA grant funding in recent years to construct similar community safe rooms.

6.2.3 Probability of Future Occurrences

The probability of future tornadoes will remain high, meaning it is likely to occur within the calendar year. Due to the unpredictability of this hazard, all buildings and infrastructure in Indiana are at risk of damage including temporary or permanent loss of function. For tornadoes, it is not possible to isolate specific essential or non-essential facilities that would be more or less vulnerable to damages.

Construction of new buildings to codes that address tornado strength winds will reduce damage in future events. Continuing efforts to increase public awareness to the dangers of tornadoes should mitigate injury, death and property losses in the future. As the population increases and more areas are developed, the potential damage from such storms will increase.
As indicated in Section 2.2.2.3, new research appears to indicate that Indiana may experience an increase in tornado activity.

### 6.3 Earthquake

An earthquake is a sudden, rapid shaking of the earth caused by the breaking and shifting of rock beneath the earth’s surface. Ninety-five percent of earthquakes occur at the plate boundaries; however, some earthquakes occur in the middle of plates, as is the case for seismic zones in the Midwestern United States. The most seismically active area in the central US is the New Madrid seismic zone. Scientists have learned that the New Madrid fault system may not be the only fault system in the central US capable of producing damaging earthquakes. The Wabash Valley Seismic Zone (Figure 69a), located near the Wabash River in southwestern Indiana and southeastern Illinois, shows evidence of large earthquakes in its geologic history, and the Anna Seismic Zone in western Ohio also has a history of moderate-sized earthquakes that could affect Indiana. There may be other currently unidentified faults that could produce strong earthquakes. Residents of Indiana could be affected both by moderate-sized earthquakes within the state’s borders, as well as by larger earthquakes with epicenters outside of the state. Both due to its proximity to the New Madrid seismic zone and exposure to the neighboring Wabash Valley seismic zone, the southwestern part of the state is considered the most earthquake-vulnerable portion of Indiana.

Earthquakes are also capable of producing a wide variety of secondary effects, including landslides and liquefaction (loss of cohesion of unconsolidated soils), fires, large waves or seiches in lakes, and damage or collapse of human structures. Many critical facilities, such as bridges, dams, and power stations, may be particularly sensitive to earthquake shaking.

Seismological research in the region suggests that a large earthquake that will seriously impact Indiana is inevitable; however, it is currently impossible to predict when such an earthquake will occur. According to one hazard model (Johnston & Nava, 1985), there is a very high probability of a moderate sized (magnitude 6.0 or greater) earthquake in the next 50 years for the central US and a much smaller likelihood (<4%) of a repeat of events similar to the New Madrid earthquakes of 1811-12. However, these estimates are highly debated, and some researchers (e.g., Newman, et al., 1999) suggest considerably lower probabilities. Nonetheless, the occurrence of moderate-sized earthquakes, including the 2002 Darmstadt, Indiana earthquake and the 2008 Mt. Carmel, Illinois earthquake, combined with evidence for larger, prehistoric earthquakes (Figure 69b) (Obermeier, et al., 1992) indicates continuing tectonic activity and the potential for infrequent, larger-magnitude events.

Ground shaking from strong earthquakes can collapse buildings and bridges, disrupt gas, electric, and phone services; and sometimes trigger landslides, flash floods, and fires. Buildings with foundations resting on unconsolidated landfill and other unstable soil, as well as trailers or homes not tied to their foundations are at risk because they can be shaken off their mountings or the soil itself can give way during an earthquake. When an earthquake occurs in a populated area, it may cause deaths, injuries, and extensive property damage. Older structures, particularly those constructed of unreinforced masonry (stone or brick) are particularly sensitive to the impacts of earthquake shaking.

Earthquake magnitude, which is determined from measurements on seismographs, measures the energy released at the source of the earthquake. Intensity measures the strength of shaking produced
by the earthquake at a certain location and is determined from effects of people, human structures, and the natural environment.

Table 40 and Table 41 define earthquake magnitudes and their corresponding intensities.

6.3.1 Historical Occurrences

Residents of Indiana have been affected by earthquakes both within the boundaries of the state and those occurring in neighboring areas of the Midwest. Prominent sources of earthquake activity include the New Madrid seismic zone, located along the Mississippi River valley in southeastern Missouri/western Tennessee and Kentucky, and the Wabash Valley seismic zone, extending along the
Wabash River valley along the Indiana/Illinois border. The New Madrid seismic zone was the site of three large (magnitude > 7) earthquakes in the winter of 1811-1812 (Johnston & Schweig, 1996; Bakun & Hopper, 2004) and is the site of continuing activity since that time, including the magnitude 6.0 Charleston, Missouri earthquake of 1895 (Street, Couch, & Konkler, 1986). There is accumulating evidence of at least three large prehistoric earthquakes in the same area (Tuttle et al., 2002). The Wabash Valley seismic zone, located closer to, and within southwestern Indiana, has been the site of numerous moderate-sized earthquakes. This includes the 1968 magnitude 5.5 Carbondale, Illinois earthquake and the April 2008 magnitude 5.2 Mt. Carmel, Illinois earthquake. There is growing evidence of larger, prehistoric earthquakes in this area as well (Obermeier, et al., 1992), as shown in Figure 69b. In addition to these zones, the Anna seismic zone in west-central Ohio (near the town of Anna, Ohio), has also been the site of continuing, moderate-level seismic activity, including a pair of magnitude ~5 earthquakes in 1937 (Schwartz & Christensen, 1988). Because of its proximity to Indiana, this zone also has the potential to affect Indiana residents in the eastern part of the state.

Figure 69. New Madrid and Wabash Valley Seismic Zones

At least 43 earthquakes, M3.0 or greater, have occurred in Indiana since 1817. The last such event was a M3.1 centered just north of Vincennes on May 10, 2010. A M3.8 earthquake occurred in December later that same year with approximately 10,390 individuals submitting felt reports to the USGS.

The majority of seismic activity in Indiana occurs in the southwestern region of the state. However, an even larger number of earthquakes originate just across the boundary in Illinois and can be felt in
Indiana. The M5.2 Mt. Carmel event on April 19, 2008, located in the Wabash Valley seismic zone, was felt by residents in Indiana, Kentucky, and many more states across the central US. The most recent event in this zone was a September 2017 M3.8 event, located at 11.7 kilometers (7.3 miles) depth. Figure 70 depicts historical earthquake epicenters in and around the state of Indiana. Instrumentally recorded earthquakes from 1975 to 2018, located using modern instruments (data from the Center for Earthquake Research and Information, University of Memphis) are shown as dark blue circles. Light blue circles denote earthquakes that occurred prior to 1975, based largely on felt effects (from the Central and Eastern United States Seismic Source Characterization for Nuclear facilities catalog at http://www.ceusssc.com). Stars represent large, prehistoric earthquake epicenters, compiled by Wheeler & Cramer (2002).

Figure 70. Historical Epicenters in Indiana

6.3.2 Vulnerability Assessment

The possibility of the occurrence of a catastrophic earthquake in the central and eastern United States is real, as evidenced by history and described throughout this section. The impacts of significant earthquakes affect large areas, terminating public services and systems needed to aid the suffering and displaced. These impaired systems are interrelated in the hardest struck zones. Power lines, water and sanitary lines, and public communication may be lost; highways, railways, rivers, and ports may not
allow transportation to the affected region. Critically, some of the most highly affected areas of southwestern Indiana are also the most dependent on major bridges crossing the Ohio and Wabash rivers for transport of goods and services in the aftermath of an earthquake; these lifelines are themselves highly vulnerable to earthquake-related damage.

Soils with little clay and a high water table may experience liquefaction, a phenomenon caused by increased pore pressures between individual soil particles. This can cause slope failures, lateral spreading, surface subsidence, and sand blows and can cause buildings to tilt or sink into the ground.

6.3.2.1 Hazus-MH Analysis

A research team from Indiana University’s Department of Earth & Atmospheric Sciences and Indiana University-Purdue University Indianapolis’ Department of Earth Sciences provided geological information and recommendations for modeling earthquake scenarios. The IU-Polis team used a combination of the US Geological Survey’s ShakeMap software and FEMA’s Hazus-MH software and performed six modeling scenarios. Two distinct approaches were applied in order to analyze seismic hazards facing the state of Indiana. The first approach uses a probabilistic earthquake hazard estimate from the U.S. Geological Survey’s (USGS) most recent (2014) edition of the National Earthquake Hazard Maps. The USGS national seismic hazard map, shown in Figure 71, indicates that the southwestern part of the state, near Evansville, is subject to the highest earthquake hazard, with the level of expected earthquake shaking gradually decreasing through the southern half of the state. The hazard is associated both with the area’s proximity to the New Madrid seismic zone and the exposure to nearby earthquakes from the Wabash valley seismic zone. The northern portion of the state is exposed to significantly lower shaking hazard.

The second approach uses a “deterministic seismic hazard assessment” to illustrate the impacts of a series of specific possible future events that might affect residents of the State of Indiana. These deterministic case studies are by definition arbitrary scenarios representing individual cases of a virtually infinite set of possible combinations of earthquake location, magnitude, source type, depth, and wave propagation characteristics that might influence the impact of earthquakes in Indiana’s future. Nonetheless, they serve to illustrate the potential impacts of particularly significant cases of geologically realistic disasters. The selection of events proposed here includes five possible scenario events, two within the state’s borders and three outside the state that could have significant impacts on Indiana’s communities.
6.3.2.1.1 7.6 Magnitude Scenario: Major New Madrid Earthquake

This event represents a large-magnitude, high-impact regional event situated in the Mississippi Valley region approximately 150 km (100 miles) from the southwestern corner of the state. The magnitude of this event (M7.6) approximates the size of the largest of the three earthquakes in the 1811-1812 New Madrid sequence (e.g., Bakun & Hopper, 2004) and is comparable to prehistoric events in the region (Tuttle, et al., 2002). Although the primary impacts would likely be felt in the states immediately surrounding the event (Missouri, Kentucky, Illinois, Tennessee), the earthquake would have impacts through the southern half of Indiana. In order to observe the maximum potential impact of the event on Indiana communities, we arbitrarily place this event in the northern segment of the New Madrid seismic zone, near Cairo, Illinois. Figure 72 shows an intensity map of this scenario, along with the location of the earthquake. Note the table at the bottom of the graphic that indicates perceived levels of shaking, reported as levels in the Modified Mercalli Intensity scale. Note that strong shaking (intensity > VII) is concentrated in the southwestern portion of the state, and that much of the southern half of the state is expected to experience at least moderate (intensity > V) levels of shaking. Expected shaking is also intensified by the presence of thick layers of unconsolidated sediment, which tend to amplify ground motions at these sites.
Hazus estimates the economic loss within the state of Indiana for the earthquake at 692.91 million dollars. The vast majority, 567 million dollars, are building-related losses. Hazus estimates that 357 buildings could be at least moderately damaged, and 40 could be damaged beyond repair. Figure 73 shows where the damage could occur. It is important to note that these losses do not represent the comprehensive economic impact of the event, as losses from social impacts such as displaced households, casualties, etc. are not taken into account. This also does not include the impacts on neighboring states, which in the case of states closer to the source (Illinois, Kentucky, Tennessee, Missouri) could be significantly higher. The regional nature of this earthquake could significantly affect our ability to get help from neighboring state emergency response agencies.

Figure 74 maps the state-owned facilities on top of the earthquake intensity map for this scenario. Some of these facilities are located in areas with more shaking than others.

Table 42 shows the estimated impact of the earthquake on essential facilities throughout the state. Four fire stations and 1 Emergency Operations Center (EOC) could suffer moderate damage. The damage to a particular facility depends on the distance to the earthquake, but also to the particular soil conditions and building construction type of that facility. Figure 75 through Figure 79 map the locations of the damaged essential facilities. Hospitals would experience minimal impact to their operations.

Figure 78. Projected New Madrid Scenario Fire Station Damage
Hazus estimates that 25 households could be displaced and 15 persons could be seeking temporary public shelter as a result of the earthquake. Additionally, Hazus estimates that a total of 50,000 tons of debris could be generated. Assuming 25 tons per truck, it would require 2000 truckloads to remove the debris generated by the earthquake.

As described in Sections 6.3.2.2 and 6.3.2.2.3, landslides and liquefaction are both secondary effects of earthquakes. Nowicki Jessee et al. (2018) developed a model for estimating the probability of landslide occurrence given ground shaking due to a particular earthquake or earthquake scenario. These modeled landslide probabilities are based on how hard the ground is expected to shake, the steepness of the ground, the type of rock present, the type of landcover present, and how wet the ground is expected to be. The distribution of predicted landslides for this scenario as calculated by the Nowicki Jessee et al. (2018) model are shown in Figure 80. The values in each location of the map indicate how much of that area is expected to landslide. The results indicate that Indiana would be subjected to only modest landslide risk, mostly associated with steep river banks in the Wabash and Ohio river valleys, and possible isolated landslide activity in areas of high relief in the south-central part of the state.

Predicted liquefaction is shown in Figure 81. The results indicate the presence of widespread liquefaction potential throughout the southwestern part of the state, centered on the areas dominated by thick unconsolidated river sediments in the Wabash and Ohio river valleys and their tributaries. This widespread liquefaction damage could affect populated areas in the Evansville, Vincennes, and Terre Haute metropolitan areas, and could have significant impact on post-earthquake transportation and utility services.

6.3.2.1.2 7.3 Magnitude Scenario: Major Wabash Valley Earthquake

This event represents a ‘worst case’ scenario of a large-magnitude event occurring along the Wabash Valley fault system, just outside the state of Indiana in southeastern Illinois. The chosen magnitude (M7.3) is significantly larger than any historic events in the region (the largest being the M5.5 southern Illinois earthquake of 1968). However, it is comparable to the largest prehistoric earthquake (M7.5, estimated age ~6,000 years before present) reported by Obermeier et al. (1992). Its location and magnitude is represented by a strike-slip earthquake rupturing the entire Mt. Carmel – New Harmony Fault system. A strike-slip fault is a vertical or nearly vertical fracture where the blocks have mostly moved horizontally. Figure 82 shows an intensity map of this scenario, along with the location of the earthquake. Note the table at the bottom of the graphic that indicates perceived levels of shaking, reported as levels in the Modified Mercalli Intensity scale. Note that strong shaking (intensity > VII) is concentrated in the southwestern portion of the state, with extremely high levels near the Indiana-Illinois border region. Much of the state is expected to experience at least moderate (intensity > V) levels of shaking. Expected shaking is also intensified by the presence of thick layers of unconsolidated sediment, which tend to amplify ground motions at these sites.

Hazus estimates the economic loss for the earthquake in Indiana at 13 billion dollars. The vast majority, almost 11 billion dollars, are building-related losses. Hazus estimates that 18,000 buildings could be at least moderately damaged, and 1,733 could be damaged beyond repair. Figure 83 shows where the damage could occur. It is important to note that these losses do not represent the comprehensive economic impact of the event, as losses from social impacts such as displaced households, casualties, etc. are not taken into account.

Figure 84 maps the state-owned facilities on top of the earthquake intensity map for this scenario. Some of these facilities are located in areas with more shaking than others.

Table 43 shows the estimated impact of the earthquake on essential facilities throughout the state. 91 hospitals, 110 schools, 8 EOCs, 26 police stations, and 67 fire stations could suffer moderate damage. The damage to a particular facility depends on the distance to the earthquake, but also to the particular soil conditions and building construction type of that facility. Figure 85 to Figure 89 map the locations of the damaged essential facilities. On the day of the earthquake, the model estimates that a portion of the beds in hospitals that sustained earthquake-related damage would be unavailable for use. 89% of the beds would likely be available for use by patients already in those facilities. After one week, 96% of the beds impacted by earthquake damage would be back in service.

Figure 88. Projected Wabash Valley Scenario Fire Station Damage
Hazus estimates that 4,408 households could be displaced and 2,713 persons could be seeking temporary public shelter as a result of the earthquake. Additionally, Hazus estimates that almost 2 million tons of debris could be generated. Assuming 25 tons per truck, it would require 75,680 truckloads to remove the debris generated by the earthquake.

The predicted landslide probabilities for this scenario are shown in Figure 90. The results indicate that portions of the southwestern part of the state would be subjected to significant landslide risk, mostly associated with steep river banks near the Wabash and Ohio river valleys, and isolated landslide activity in areas of high relief in the south-central part of the state.

Predicted liquefaction is shown in Figure 91. The results indicate the presence of widespread liquefaction potential throughout the southwestern part of the state, centered on the areas dominated by thick unconsolidated river sediments in the Wabash and Ohio river valleys and their tributaries. The widespread liquefaction damage could affect populated areas in the Evansville, Vincennes, and Terre Haute metropolitan areas, and could have significant impact on post-earthquake transportation and utility services.
Figure 90. Projected Wabash Valley Scenario Landslide Risk
Figure 91. Projected Wabash Valley Scenario Liquefaction Risk
6.3.2.1.3 Magnitude Scenario: Anna, Ohio Earthquake

This scenario represents a moderate-sized (M6.2) event located just west of the Indiana-Ohio border near Anna, Ohio. This site is selected to represent a known seismic zone associated with current seismic activity (Schwartz & Christensen, 1988). The scenario earthquake is located at 15 km depth near the epicenter of the largest of the March, 1937 earthquakes (M5.5) and close to the Auglaise fault and the Fort Wayne Rift, which may be the source of these intraplate events. The earthquakes were strongly felt in Ohio, Indiana, Michigan, and Kentucky, and produced minor damage in the epicentral region. The magnitude is significantly higher than reported earthquakes in the area, but smaller than the maximum magnitude estimated by the US Geological Survey for stable continental interior regions of the central-eastern U.S. (Moschetti, et al., 2015). Unlike the Wabash Valley seismic zone, there have been no comprehensive paleoseismic studies in this area to constrain the history and magnitude of prehistoric earthquakes in the area.

Figure 92 shows an intensity map of this scenario, along with the location of the earthquake. Note the table at the bottom of the graphic that indicates perceived levels of shaking, reported as levels in the Modified Mercalli Intensity scale. Note that strong shaking (intensity > VII) is concentrated outside the boundaries of the state, but that moderate (intensity > V) levels of shaking would be experienced in the east-central part of the state, including Muncie and Fort Wayne. Expected shaking is also intensified by the presence of thick layers of unconsolidated sediment, which tend to amplify ground motions at these sites.

Hazus estimates the economic loss for the earthquake at 246 million dollars. The majority, 170 million dollars, are building-related losses. Hazus estimate that 17 buildings could be at least moderately damaged. Figure 93 shows where the damage could occur. It is important to note that these losses do not represent the comprehensive economic impact of the event, as losses from social impacts such as displaced households, casualties, etc. are not taken into account.

Figure 94 maps the state-owned facilities on top of the earthquake intensity map for this scenario. Some of these facilities are located in areas with more shaking than others.

Table 44 shows the estimated impact of the earthquake on essential facilities throughout the state. None are modeled to suffer moderate damage. The damage to a particular facility depends on the distance to the earthquake, but also to the particular soil conditions and building construction type of that facility. Figure 95 to Figure 99 map the locations of the damaged essential facilities. Hospitals would experience minimal impact to their operations.

Hazus estimates that no households could be displaced nor seeking temporary public shelter as a result of the earthquake. Additionally, Hazus estimates that a total of 3,000 tons of debris could be generated. Assuming 25 tons per truck, it would require 120 truckloads to remove the debris generated by the earthquake.

Because of its modest size and distance from Indiana, the earthquake is not expected to have significant landslide impacts within the state (see Figure 100). However, the earthquake could produce some liquefaction damage, as shown in Figure 101. The results indicate the presence of modest liquefaction potential in the east-central part of the state, centered on the areas dominated by thick unconsolidated river sediments in the Wabash river valley and its tributaries. This widespread liquefaction damage could affect populated areas in the Evansville, Vincennes, and Terre Haute metropolitan areas, and could have significant impact on post-earthquake transportation and utility services.
Figure 100. Projected Anna, Ohio Scenario Landslide Risk
Figure 101. Projected Anna, Ohio Scenario Liquefaction Risk
6.3.2.1.4 6.2 Magnitude Scenario: Darmstadt (Evansville) Earthquake

This scenario represents a moderate-sized earthquake located close to one of Indiana’s most seismically vulnerable cities. The location was chosen to match the epicentral location of the June, 2002 M5.0 earthquake (Kim, 2003), which was strongly felt in southern Indiana and neighboring areas of Kentucky and Illinois. The earthquake magnitude (M6.2) was chosen to represent a reasonable-case large earthquake that could occur close to the city of Evansville. While the magnitude is somewhat larger than any historic events in the region (the largest being the M5.5 southern Illinois earthquake of 1968), it is significantly smaller than the largest prehistoric earthquake (M7.1, estimated age ~14,000 years before present) reported by Obermeier et al. (1992). It is represented by a strike-slip earthquake rupturing the neighboring Caborn Fault.

Figure 102 shows an intensity map of this scenario, along with the location of the earthquake. Note the table at the bottom of the graphic that indicates perceived levels of shaking, reported as levels in the Modified Mercalli Intensity scale. Note that strong shaking (intensity > VII) is concentrated in the Evansville area, with much of the southwestern third of the state expected to experience at least moderate (intensity > V) levels of shaking. Expected shaking is also intensified by the presence of thick layers of unconsolidated sediment, which tend to amplify ground motions at these sites.

Hazus estimates the economic loss for the earthquake at almost 11 billion dollars. The vast majority, almost 10 billion dollars, are building-related losses. Hazus estimates that 16,648 buildings could be at least moderately damaged, and 1,151 could be damaged beyond repair. Figure 103 shows where the damage could occur. It is important to note that these losses do not represent the comprehensive economic impact of the event, as losses from social impacts such as displaced households, casualties, etc. are not taken into account.

Figure 104 maps the state-owned facilities on top of the earthquake intensity map for this scenario. Some of these facilities are located in areas with more shaking than others.

Table 45 shows the estimated impact of the earthquake on essential facilities throughout the state. 36 hospitals, 75 schools, 1 EOC, 13 police stations, and 32 fire stations could suffer moderate damage. The damage to a particular facility depends on the distance to the earthquake, but also to the particular soil conditions and building construction type of that facility. Figure 105 to Figure 109 map the locations of the damaged essential facilities. Hospitals would experience minimal impact to their operations.

Hazus estimates that 5,601 households could be displaced and 3,435 persons could be seeking temporary public shelter as a result of the earthquake. Additionally, Hazus estimates that almost 1.7 million tons of debris could be generated. Assuming 25 tons per truck, it would require 67,360 truckloads to remove the debris generated by the earthquake.

Predicted landslide probabilities for this scenario are shown in Figure 110. The results indicate that there would not be widespread landslide activity, but that areas of high relief to the west and north of Evansville may be subjected to significant landslide risk.

Predicted liquefaction is shown in Figure 111. These results indicate the presence of widespread liquefaction potential throughout the southwestern part of the state, centered on the areas dominated by thick unconsolidated river sediments in the Wabash and Ohio river valleys and their tributaries. This widespread liquefaction damage could affect populated areas in the Evansville and Vincennes metropolitan areas, and could have significant impact on post-earthquake transportation and utility services.
Figure 110. Projected Darmstadt Scenario Landslide Risk
Figure 111. Projected Darmstadt Scenario Liquefaction Risk
### 6.3.2.1.5 5.8 Magnitude Scenario: Central Indiana Earthquake

This moderate event was chosen to represent the possible occurrence of a moderate-sized (M5.8) earthquake that could, in principle, occur anywhere within the state. The earthquake size is comparable to the largest earthquakes that have occurred in the region (including the 1937 Anna, Ohio sequence and the 1965 southern Illinois earthquake), and well below the maximum magnitude used for “background” seismic activity in the stable continental interior of the central U.S. (Petersen, et al., 2014). While the location is arbitrary, it is placed close to the surface location of the Fortville Fault, which extends for about 50 km (30 miles) in a NE direction from central Marion County (West & Warder, 1983). The earthquake is chosen to illustrate the potential effects of a moderate-magnitude event within a densely populated urban setting.

Figure 112 shows an intensity map of this scenario, along with the location of the earthquake. Note the table at the bottom of the graphic that indicates perceived levels of shaking, reported as levels in the Modified Mercalli Intensity scale. Note that strong shaking (intensity > VII) is concentrated in a very localized area surrounding the epicenter, but that a much larger area, extending to 30-50 miles from the epicenter, is expected to experience at least moderate (intensity > V) levels of shaking. Expected shaking is also intensified by the presence of thick layers of unconsolidated sediment, which tends to amplify ground motions at these sites.

Hazus estimates the economic loss for the earthquake at almost 20 billion dollars. The vast majority, almost 19 billion dollars, are building-related losses. Hazus estimates that 18,769 buildings could be at least moderately damaged, and 1,441 could be damaged beyond repair. Figure 113 shows where the damage could occur. It is important to note that these losses do not represent the comprehensive economic impact of the event, as losses from social impacts such as displaced households, casualties, etc. are not taken into account.

Figure 114 maps the state-owned facilities on top of the earthquake intensity map for this scenario. Some of these facilities are located in areas with more shaking than others.

Table 46 shows the estimated impact of the earthquake on essential facilities throughout the state. 158 hospitals, 108 schools, 14 fire stations and 8 police stations could suffer moderate damage. The damage to a particular facility depends on the distance to the earthquake, but also to the particular soil conditions and building construction type of that facility. Figure 115 to Figure 119 map the locations of the damaged essential facilities. On the day of the earthquake, the model estimates that a portion of the beds in hospitals that sustained earthquake-related damage would be unavailable for use. 86% of the beds would likely be available for use by patients already in those facilities. After one week, 93% of the beds impacted by earthquake damage would be back in service.

Hazus estimates that 5,696 households could be displaced and 3,765 persons could be seeking temporary public shelter as a result of the earthquake. Additionally, Hazus estimates that 2 million tons of debris could be generated. Assuming 25 tons per truck, it would require 80,320 truckloads to remove the debris generated by the earthquake.

Predicted landslide probabilities for this scenario are shown in Figure 120. Because of the localized nature of this earthquake, widespread landslide activity is not expected. These results suggest that a few areas of high relief near Indianapolis may be subjected to moderate landslide risk, mostly associated with steep river banks near the White River and Fall Creek river valleys.

Predicted liquefaction is shown in Figure 121. The results indicate the presence of localized but significant liquefaction potential throughout Central Indiana, particularly in the areas dominated by thick unconsolidated river sediments in the White River and Sugar Creek river valleys and their tributaries. This liquefaction damage could affect populated areas in the Indianapolis metropolitan areas, and could have significant impact on post-earthquake transportation and utility services.
SECTION 6: NATURAL HAZARDS

Figure 120. Projected Central Indiana Scenario Landslide Risk
Figure 121. Projected Central Indiana Scenario Liquefaction Risk
6.3.2.1.6 500-Year Probabilistic Scenario

This scenario seeks to represent the cumulative hazard facing each area of the state based on a probabilistic likelihood of ground shaking associated with all of the sources that could potentially affect a given area. Shown here is the estimated ground shaking associated a .2% annual probability of exceedance (equivalent to a 500-year return period). In principle, this analysis evaluates the average impacts of a multitude of possible earthquake sources with a magnitude that would be typical of that expected for a 500-year return (.2% probability).

Hazus estimates the economic loss for the earthquake at just shy of 3 billion dollars. The vast majority, about 2.5 million dollars, are building-related losses. Hazus estimates that 6,576 buildings could be at least moderately damaged, and 32 could be damaged beyond repair. Figure 122 shows where the damage could occur. It is important to note that these losses do not represent the comprehensive economic impact of this probabilistic scenario, as losses from social impacts such as displaced households, casualties, etc. are not taken into account.

Table 47 shows the estimated impact of the earthquake on essential facilities throughout the state. None are modeled to suffer moderate damage. The damage to a particular facility depends on the distance to the earthquake, but also to the particular soil conditions and building construction type of that facility. Figure 123 to Figure 127 map the locations of the damaged essential facilities. On the day of the earthquake, the model estimates that a portion of the beds in hospitals that sustained earthquake-related damage would be unavailable for use. 86% of the beds would likely be available for use by patients already in those facilities. After one week, 95% of the beds impacted by earthquake damage would be back in service.

Figure 126. Projected 500-Year Probabilistic Scenario Fire Station Damage
Hazus estimates that 930 households could be displaced and 577 persons could be seeking temporary public shelter as a result of the composite earthquake hazard. Additionally, Hazus estimates that over 400,000 million tons of debris could be generated. Assuming 25 tons per truck, it would require 17,360 truckloads to remove the debris generated by the earthquake.

### 6.3.2.2 Earthquake Secondary Effects

The primary damage caused by an earthquake is associated with the ground motion caused by seismic waves. Most earthquake damage results when those seismic waves pass beneath buildings, roads, and other structures. For example, ground shaking may cause a building’s exterior walls to crumble, injuring people, blocking sidewalks and streets and bringing down utility lines. The earthquake impacts are highly variable, depending on a site’s location relative to the earthquake. Damages at a particular site are determined by the earthquake source parameters (magnitude, duration of shaking, depth), the distance to the site, and the local site conditions (including what type of Earth material is present at that location).

These factors contribute to generate the spatial variation of ground motions (represented by ground acceleration or intensity). The direct impact of the earthquake depends largely on the characteristics of affected buildings in which people live or work, including the building use, design type, occupancy, year of construction, height, floor plan, etc. For instance, older buildings constructed of unreinforced brick or stone are particularly vulnerable to earthquake-related damage. Newer construction types with more flexible building materials such as steel or wood tend to be more resistant to the effects of ground vibration.
Earthquake-resistant construction is one of the main ways of reducing the enormous destructive potential of earthquakes and the threat they pose to human life. Rigorous building codes for exposed regions, and enforcement of those codes, are essential to widespread implementation of state-of-the-art earthquake-resistant building methods.

In addition to the primary impacts of the ground-shaking on buildings, strong earthquakes often trigger serious secondary effects which also have a high potential for damage and loss of life. They are often the prime factor for determining whether an earthquake is categorized as a catastrophe. These are the main secondary effects: fire, landslide, liquefaction, and tsunami and seiches.

### 6.3.2.2.1 Fires

Fire has long been recognized as a major hazard following earthquakes. Earthquake shaking can rupture gas lines, trigger electrical sparks, upset burning candles, stoves and fireplaces. The effects of fire can in some cases be more severe than the primary impacts of the earthquake shaking. Perhaps the most infamous earthquake-initiated fires in US history burned much of the City of San Francisco in the aftermath of the 1906 earthquake. Up to 90% of building damage after the earthquake was attributed to the fires and the crude firefighting techniques employed in an effort to contain the blaze. In addition to their direct impacts, earthquakes can block access to fire-fighting equipment and damage water supplies, making fighting the blazes, of which there might be many across a city, especially challenging. The potential impacts of post-earthquake fires are, in principle, incorporated into the damage estimates provided by the Hazus models discussed in the previous section.

### 6.3.2.2 Landslides

Earthquakes can trigger landslides, especially in areas with steep slopes and water-saturated soils, often associated with river banks or other areas of high relief. Landslides may result in falling rocks, soils, and fluid masses that impact people, buildings and vehicles. They also can block roads, temporarily dam streams, and disrupt utility lines. In general, areas of landslide risk are associated with the zones of strongest ground motion and zones of high relief and weak soils.

### 6.3.2.3 Liquefaction

Soil liquefaction is a secondary effect of earthquakes in which the strength of a soil is modified by earthquake shaking. Liquefaction and related phenomena have been responsible for tremendous amounts of damage in historical earthquakes around the world. Particularly notable is the damage associated with the 2011 Christchurch, New Zealand earthquake, in which large areas of the city were damaged by liquefaction-related ground failure.

Liquefaction is a process that turns normally solid soils in “quicksand.” The process occurs in soils that are saturated with water. Prior to an earthquake, the pressure in the soil pore spaces is relatively low—the weight of the buried soil rests on the framework of grain contacts that comprise it. However, earthquake shaking can disrupt the structure, the soil particles no longer support all the weight, and the groundwater pressure begins to rise and the soil particles can become entrained in the water and flow. Liquefied soil will force open ground cracks in order to escape to the surface in the form of “mud volcanoes” or “lateral spreads”. The ejected material often results in flooding and may leave cavities in the soil.
Figure 128. Liquefaction Potential (Gray et al., 2012)
Whether and where liquefaction will take place depends on many factors. These include (1) the degree of saturation, (2) the distribution of soil grain sizes, (3) the strength, duration, and frequency content of the shaking and even the grain shape and depth of soil. The vulnerability to soil liquefaction can be determined based on these characteristics. A map of relative liquefaction potential for Indiana, based on the composition and thickness of unconsolidated soils throughout the state is presented in Figure 128. The potential impacts of post-earthquake liquefaction are, in principle, incorporated into the damage estimates provided by the Hazus models discussed in the previous section.

### 6.3.2.2.4 Disruptions

The primary impacts of earthquakes have the potential to destroy roads and bridges, disrupt power grids and other utilities, and shut down manufacturing and production plans in the affected areas. These disruptions may, in turn, impact the delivery of life critical products and services such as groceries, water, heating and cooling, availability of prescription drugs, and access to medical care. The duration of these large scale disruptions could be hours, days, or even weeks until temporary repairs or workarounds are made to essential systems. The impact to human and animal health may be significant, especially to those injured by the primary impacts of the earthquake event, and will worsen over a longer term disruption period.

### 6.3.2.2.5 Tsunami and Seiches

One of the most severe secondary effects of earthquakes in oceanic areas are tsunamis, which are earthquake-triggered sea waves. Inland earthquakes will not result in tsunamis because they do not uplift the seafloor. However, they can trigger seiches, which are standing waves in lakes. A seiche (pronounced: saysh) is a standing wave in any enclosed or partially enclosed body of water. Triggered by earthquake waves, seiches and seiche-related phenomena have been observed on lakes, reservoirs, swimming pools, bays, harbors, and seas. The key requirement for formation of a seiche is that the body of water be at least partially bounded, allowing the formation of the standing wave. They can produce damage to boats, piers, and structures close to the shoreline of a lake.

### 6.3.2.3 Induced Seismicity

In addition to the occurrence of naturally occurring earthquake activity, Indiana residents could be affected by “induced seismic activity,” the process by which human activity affects the ambient state of stress in the earth’s crust enough to trigger earthquakes. Although this phenomenon has been well documented for many years (e.g., Healy, Rubey, Griggs, & Raleigh, 1968), there has been a pronounced increase in induced seismic activity over the past decade, associated in particular with subsurface injection of fluids associated with oil and gas production (Ellsworth, 2013; National Research Council, 2013; Ground Water Protection Council, 2015). Other engineering activities, such as impoundment of reservoirs and mining, construction, or weapons testing explosions, also have the potential of inducing seismicity (National Research Council, 2013). Future activity associated with underground storage of carbon dioxide also has the potential to produce induced seismic activity. Well documented cases of induced seismic activity have been observed throughout the Midwest, including occurrences in Ohio, Arkansas, Texas, Oklahoma, and Kansas, including some cases of damaging earthquakes. Although small earthquakes have been linked to the process of hydraulic fracturing (or “fracking”), larger events are typically associated with large-volume wastewater injection. The high volume of wastewater is produced either as a result of the hydraulic fracturing or as a byproduct of petroleum production.
Induced earthquakes are, in essence, the equivalent of naturally occurring earthquakes whose timing has been triggered by human activity. Factors influencing the occurrence of induced earthquakes include the durations and volumes of injection, spatial proximity of injection to active faults, and changes in hydraulic pressures that bring the faults to failure. In the central United States, the occurrence of small- and moderate-magnitude earthquakes had been mostly constant from the 1960s until the turn of the century; that rate showed a significant increase in 2001, followed by a rapid acceleration in 2010 (Figure 129). Ellsworth, 2013, among others, attributes this rise in earthquake numbers to induced seismicity associated with increased oil and gas activity in the central United States.

Figure 129. Induced Earthquakes in the Central United States

Evidence of induced seismic activity in the Central U.S. (A) Cumulative count of earthquakes as a function of time in the central and eastern United States, 1967–2012 (earthquakes in the area studied shown in inset). The dashed line corresponds to the long-term average rate of earthquakes occurrence. Note the substantial increase in activity beginning in 2008. From Ellsworth (2013) (B) Comparison of induced vs. naturally occurring earthquakes. Gray bars represent the number of earthquakes per year in the central U.S. from 1973 to 2014. The red bars represent the number of earthquakes that are associated with wastewater injection wells. The black line denotes the number of naturally occurring earthquakes per year. Note the significant increase in 2011 through 2014, a result of enhanced oil and gas exploration in the region. From Weingarten et al. (2015).

A recent study by the Indiana Geological and Water Survey (Rupp et al., 2016) summarized the state of knowledge about induced seismic activity in the state. Like many of our neighboring states, Indiana is an oil- and gas-producing state that also disposes of wastewater related to oil production through subsurface injection. Compared to other states, Indiana shows limited evidence of earthquakes that are associated with these practices. Indiana has not been identified by the USGS annual assessment of short-term induced seismicity hazards (Petersen, et al., 2018). However, at least one research study (Weingarten et al., 2015) provided circumstantial evidence for induced earthquakes in Indiana and Illinois; a second study (Eagar et al., 2006) suggested that the occurrence of a swarm of very small-magnitude earthquakes in the mid-1990s along the Wabash River in southwestern Indiana may have
been triggered by oil and gas exploitation in the region. Because the majority of the wastewater injection wells (Figure 130) are located in the southwestern part of the state (Figure 131)—the area most heavily dominated by active natural seismic activity—it is in the state’s best interest to monitor wastewater injection and seismic activity within Indiana so that any future activity can be assessed with high-quality observational data. The wells with the highest rates and volumes of wastewater injection are those with the highest potential for future induced seismicity. Wastewater injection practices are monitored by the Division of Oil & Gas, a regulatory agency of IDNR. As in other states affected by induced earthquake activity, occurrences of documented induced seismic activity could result in modification or termination of wastewater injection at neighboring wells.

6.3.3 Probability of Future Occurrences

The probability of future earthquakes occurring is unknown. The USGS asserts that a large earthquake that will seriously impact southwestern Indiana is inevitable; however, it is currently impossible to predict when such an earthquake will occur. According to the USGS, there is a 25 to 40% chance of a magnitude 6.0 or greater earthquake in the next 50 years for the central US. There is a 7 to 10% chance of a repeat of events similar to the New Madrid earthquakes of 1811-12.

Future earthquake events will affect larger populations, business development, and aged vulnerable infrastructure. Upgraded building codes will protect newer construction, but much of the population will remain vulnerable because of low public interest in earthquake safety due to the relative inactivity of the fault systems, which presents a serious problem.
Figure 130. Indiana Class II Injection Wells Active from 2004 to 2014 (Rupp et al., 2016)
6.4 Extreme Temperatures

Extreme temperatures—both hot and cold—can have significant impact on human health and safety, commercial businesses, agriculture, and primary and secondary effects on infrastructure (e.g. burst pipes, power failures, etc.). Weather conditions described as extreme heat or cold vary across different areas of the state, based on the range of average temperatures within the region.

Extreme Heat

According to the Centers for Disease Control and Prevention (CDC), there is no single agreed upon definition of an extreme heat event. These events typically refer to an extended period of time, such as several days or more, with unusually hot weather conditions that can potentially harm human health. Heat alert procedures are based primarily on Heat Index Values. The Heat Index—given in degrees Fahrenheit—is often referred to as the apparent temperature and is a measure of how hot it really feels...
when the relative humidity is factored with the actual air temperature. The NWS Heat Index Chart can be seen below in Figure 132.

**Figure 132. National Weather Service Heat Index Chart**

**Extreme Cold**

What constitutes an extreme cold event, and its impacts, varies across the United States. In areas unaccustomed to winter weather, near freezing temperatures are considered “extreme cold.” Extreme cold temperatures are typically characterized by the ambient air temperature dropping to approximately 0 degrees Fahrenheit or below.

The magnitude of extreme cold temperatures is generally measured through the Wind Chill Temperature (WCT) Index. WCT is the temperature that is felt when outside and is based on the rate of heat loss from exposed skin by the effects of wind and cold. As the wind increases, the body is cooled at a faster rate causing the skin’s temperature to drop.

The index, shown in Figure 133, includes a frostbite indicator, showing points where temperature, wind speed, and exposure time will produce frostbite in humans.
6.4.1 Historical Occurrences

Indiana experienced 14 excessive heat events from 2008 through 2018 according to the NCDC, 11 of those from 2010 through 2012. The last event occurred on July 5, 2018. The 2012 heat wave was particularly severe and resulted in 82 heat-related deaths in the United States and Canada. Fort Wayne tied its all-time record high with 106°F and Indianapolis broke its monthly record at 104°F.

There were 10 extreme cold/wind chill events in Indiana from 2008 through 2018 according to the NCDC, with 7 of those since 2014. On January 1, 2018, the jet stream moved south and led to a new low temperature record of -12°F for Indianapolis and -15°F for South Bend.

6.4.2 Vulnerability Assessment

One of the cascading events of extreme cold temperatures over a long period of time is the formation of ice dams that result in damage to bridges and other infrastructure. In extreme events, ice will damage residential and commercial structure foundations, but the typical result in Indiana is flash flooding. The flooding may be further exacerbated if the ice dam “self-destructs” or officials are forced to intervene to open the channel.

Extreme temperature events often lead to severe short and long term health conditions, or even death, particularly for special needs populations and the elderly. Urban populations are particularly vulnerable because of elevated temperatures in cities—known as the “urban heat island effect”—caused by lack of tree cover and the magnifying effect of heat on paved surfaces. However, extreme temperatures can occur within any area in the state; therefore, the entire state population and all buildings are vulnerable to extreme temperature hazards.

According to the NWS, extreme heat is the number one cause of weather-related fatalities in the United States over the past 30 years, with an average of 134 per year (see Figure 134).
6.4.3 Probability of Future Occurrences

The probability of future extreme temperatures is medium, meaning it is probable to occur within the next 5 years. According to the 2018 Indiana Climate Change Impacts Assessment, extreme cold events are predicted to decline while the number of extremely hot days will rise.

6.5 Drought

Droughts are created by below normal rainfall; however, excessive heat can lead to increased evaporation, which will enhance drought conditions. A drought can occur in any month and is the consequence of a reduction in the amount of precipitation over an undetermined length of time (usually a growing season or more). The severity of a drought depends on location, duration, and geographical extent. Additionally, drought severity depends on the water supply, usage demands made by human activities, vegetation, and agricultural operations.

Indiana is increasingly vulnerable to drought hazards due to growth and shifts in population; land use changes, which can result in water shortage and degrade water quality; and climate change, which increases the frequency, severity, and duration of drought events.

The US Drought Monitor categorizes droughts on a scale from D0 to D4 as outlined in Table 48.

#### 6.5.1 Historical Occurrences

Since 2008, there have been 22 separate drought events reported to the NCDC (see Figure 135). There were no reports of deaths, injuries, or crop damage in NCDC records. All but one of these drought events occurred from 2010 to 2012. The latest recorded drought was in November 2016, affecting the southern Indiana counties of Pike, Spencer, Vanderburgh, Warrick, Gibson, and Posey. Its drought category was at most a D1.

Indiana’s most recent significant drought occurred in 2012. The month of March was characterized by record-breaking warmth, which resulted in an early start to the growing season. This, combined with lack of precipitation from the 2011-2012 winter, led to abnormally dry conditions across the state in April. From July through December more than half of the state was under a moderate drought (D1) or worse. In July, 51% of the state experienced a severe drought, and in August, 7% of the state was in an exceptional drought. Figure 136 illustrates the status of the drought at its worst on July 31, 2012. Lack of rainfall and extreme temperatures devastated crops and impaired livestock feed and water supplies across Indiana.

*Figure 135. US Drought Monitor Indiana Time Series*
Figure 136. July 31, 2012 Drought Status (Source: US Drought Monitor)
6.5.2 Vulnerability Assessment

The hazard extent for a drought is statewide; therefore, all communities and infrastructure are vulnerable. Communities are often reactive in their approach to drought planning. Instead of developing detailed and comprehensive mitigation strategies for future droughts, they respond to imminent droughts by implementing strategies (e.g., burn bans and water restrictions) that do little to minimize the costs of response and recovery.

Drought impacts on corn and soybeans crops can be assessed using the NCDC’s Crop Moisture Stress Index (CMSI), which is calculated through the use of a drought index (Palmer Z Index) and annual average crop productivity values within each US climate division. Moisture stress, either a lack or an abundance of, can critically affect crop growth and development.

Figure 137 and Figure 138 show the corn and soybean moisture stress index for the US from 1900 to 2018.

*Figure 137. Corn Moisture Stress Index*
6.5.3 Probability of Future Occurrences

The probability of future droughts is medium, meaning it is probable to occur within the next 5 years. While the state has not experienced significant droughts since the last plan update in 2014, the 2018 IN CCIA predicts that with temperature increases reduced summer precipitation, and increased water demand, soil moisture will decrease, leading to drought or drought-like conditions.

6.6 Winter Storm

Severe winter weather consists of various forms of precipitation and strong weather conditions. This may include one or more of the following: freezing rain, sleet, heavy snow, blizzards, icy roadways, extreme low temperatures, and strong winds. These conditions can cause human health risks such as frostbite, hypothermia, and death.

Ice Storms

Ice or sleet, even in the smallest quantities, can result in hazardous driving conditions and can be a significant cause of property damage. Sleet can be easily identified as frozen raindrops. Sleet does not stick to trees and wires. The most damaging winter storms in Indiana have been ice storms. Ice storms are the result of cold rain that freezes on contact with objects having a temperature below freezing. Ice storms occur when moisture-laden gulf air converges with the northern jet stream, causing strong winds...
and heavy precipitation. This precipitation takes the form of freezing rain, coating power lines, communication lines, and trees with heavy ice. The winds then will cause the overburdened limbs and cables to snap, leaving large sectors of the population without power, heat, or communication. Falling trees and limbs also can cause building damage during an ice storm. In the past few decades, numerous ice-storm events have occurred in Indiana.

**Snowstorms**

Significant snowstorms are characterized by the rapid accumulation of snow, often accompanied by high winds, cold temperatures, and low visibility. A blizzard is categorized as a snowstorm with winds of 35 miles an hour or greater and/or visibility of less than one-quarter mile for three or more hours. The strong winds during a blizzard blow about falling and already existing snow, creating poor visibility and impassable roadways. Blizzards have the potential to result in property damage.

Indiana has been struck repeatedly by blizzards. Blizzard conditions not only cause power outages and loss of communication, potentially for days, but can also make transportation difficult. The blowing of snow can reduce visibility to less than one-quarter mile, and the resulting disorientation makes even travel by foot dangerous, if not deadly.

Damages from blizzards can range from significant snow removal costs to human and livestock deaths. Because of the blinding potential of heavy snowstorms, drivers are also at risk of collisions with snowplows or other road traffic. Stranded drivers can make uninformed decisions, such as leaving the car to walk in conditions that put them at risk. Drivers and homeowners without emergency plans and kits are vulnerable to the life-threatening effects of heavy snow storms such as power outages, cold weather, and inability to travel, communicate, obtain goods or reach their destinations. Heavy snow loads can cause structural damage, particularly in areas where there are no building codes or for residents living in manufactured home parks.

### 6.6.1 Historical Occurrences

#### 6.6.1.1 Ice Storms

Based on NCDC data since 1996, Indiana is at risk of ice storms from December through February, with just one ice storm recorded in March. Particular bad years were 2007 and 2008, with 5 and 3 storms respectively. Most years see on average 1 recorded ice storm.

From January 31 to February 2, 2011, up to an inch of ice fell across parts of central Indiana. Over 80,000 residents lost power, some for days.

#### 6.6.1.2 Snowstorms

Indiana can experience snowfall during most years from November through March, especially in the lake effect snow belt in the northern part of the state. Snow has occurred as early as September and as late as May, although these events are rare. The first measurable snowfall of the season usually occurs by the start of November in northern Indiana and by mid-November in southern Indiana.

NOAA’s NCDC produced a Regional Snowfall Index (RSI) for significant snowstorms that impact the eastern two-thirds of the US. This index is similar to the Enhanced Fujita scale (tornadoes) and Saffir-Simpson scale (hurricanes) but differs from these indices because it takes into account. RSI is based on the spatial extent of a storm, the amount of snowfall, and population from the 2000 Census. The RSI is
based on the spatial extent of the storm and the amount of snowfall and considers how these elements interact with an area’s population (Table 49). It is produced for each of the six NCDC climate regions (Figure 139).

**Table 49. Regional Snowfall Index**

</tbody>
</table>

Since 2008, the NCDC has reported 37 snowstorms in the Ohio Valley region (see Figure 139). The vast majority (26 or 70%) were category 1 storms, seven were category 2, three were category 3 and one was a category 5. The most recent category 2 or above storm was the January 2016 blizzard that mainly impacted the mid-Atlantic and northeastern states. Seven states saw snowfall in excess of 30 inches and at least 55 people were killed in storm-related incidents. The southern Indiana counties of Pike, Warrick, Spencer, Perry, Crawford, Harrison, Floyd, and Clark counties saw heavy snow with accumulations of 4 to 5 inches. This storm’s RSI was almost 9.96.

From January 5 to 9, 2014, a category 3 snowstorm impacted Indiana. The northern third of the state experienced 10 to 17 inches of snow accumulations. This storm’s RSI was 8.4.

**Figure 139. NCDC Climate Regions**
6.6.2 Vulnerability Assessment

The hazard extent of a winter storm is statewide, but is historically more severe in northern Indiana due to lake effect snow. Therefore, communities and infrastructure in the northern part of the state are at greater risk than in the southern part of the state. Heavy snow causes many problems for the public. Snowfall rates can exceed an inch per hour. As these systems intensify, wind speeds can approach hurricane force (74 mph). The blowing and drifting snow that results can paralyze a region. Automobiles are stranded on highways and peoples’ lives are at risk in the absence of adequate shelter. With roads impassable, travel may be restricted for significant periods.

To further compound risks, cold air moving south behind the retreating low pressure area can cause temperatures to plummet. As the arctic high pressure area behind the low builds into the region temperatures can fall to 20 to 30 degrees below normal. A cold air mass can stay over the region for up to a week, until the next weather system moves in. These conditions can tax utility systems that are already working at peak output.

The weight of the snow itself can also be a problem, especially if the snow has a high water content. Tremendous weight of snow from significant storms can cause structures to collapse. Tree branches, especially on fully-leaved trees, can easily break under the weight of heavy snow. For example, if a snow cover of 12 inches has a water equivalent of 1.0 inch of water it would weigh 5.2 pounds per square foot. Additional snowfall would continue to increase this weight and structures could eventually become stressed. Flat roofs are especially susceptible to this problem but sloping roofs, especially if the structural components are weak, can also be damaged.

- **Population Exposure** - Historical information indicates that the entire state is at risk of winter storms. Winter storms affect mostly humans, particularly special needs populations, and animals due to lack of mobility or isolation from supplies. They are more reliant upon the roads and vehicular travel for access to needed supplies. Lack of communication due to downed phone and power lines, will further isolate and make obtaining assistance more difficult if needed.
- **Human Services** - The loss of usual means of transportation to provide emergency services and the dependence upon back-up power systems will be the first of many impacts upon the Human Service Agencies. The lack of reliable communications and personnel to staff and provide services paired with increased demand for services they provide may overwhelm smaller agencies and tax many larger agencies to near exhaustion.
- **Transportation Exposure** - The transportation network will be the first impacted. Snow and ice accumulations will make travel along these systems difficult or impossible. These types of storms do not usually destroy this type of infrastructure, but rather result in temporary effects. The problem is normally debris related. The freeze thaw of winter and its related damage to roads is normal and planned for throughout the state. Transportation is more likely to be affected by cascading events, such as debris from ice storms or flooding from excessive snowmelt.
- **Utility Infrastructure Exposure** - A community’s infrastructure is likely to experience the most physical damage. Power and communication equipment are vulnerable to winds, but the addition of ice on the lines quickly renders the community without power or communication. The loss of power may mean that communities and individuals may not have water, since it
takes electricity to convey it to the customer. Towns and cities depend upon electricity to pump, treat and deliver water to their citizens.

- **Economic Exposure** - Economically, industry and agriculture can suffer the effects of a winter storm. Both are dependent on transportation. The collapse of structures due to snow loading, loss of man-hours and inability to ship goods, receive material or to receive orders for goods and services will impact the economic community. Historically, Indiana has suffered agriculturally from loss of livestock or crops due to winter storms and cascading events such as flooding.

The loss potential to above-ground infrastructure could be devastating. The lack of past history of frequent severe winter storms does not provide a large sample of information upon which to base loss estimates. The January 2014 severe winter storm and snowstorm resulted in a federal disaster declaration (DR-4173) for 30 Indiana counties. Almost $10 million of public assistance were approved. Winter storms in Indiana normally are not long-term recovery programs. These events typically only require emergency snow and debris removal. They can also be deadly due to exposure, fire, carbon monoxide poisoning, and transportation accidents.

The lack of public awareness, preparedness, and mitigation will result in increased losses as the population and the dependence upon technology continues. The recovery time to restore power and communication infrastructure can be improved by the requirement that electric and communications service lines be buried. The lack of heat in residences and the exposure to cold is the greatest threat to people. Public education on the dangers of alternative heating systems, and what to do if caught outside during a storm would reduce the risk to the population. These programs can prevent the state’s exposure to loss from these storms from increasing as the population increases.

### 6.6.3 Probability of Future Occurrences

The probability of future winter storms will remain high, meaning it is likely to occur within the calendar year. Due to the unpredictability of this hazard, all buildings and infrastructure in Indiana are at risk of damage including temporary or permanent loss of function. While current climate predictions indicate increased precipitation, especially in the winter and spring, it is expected that rain will replace snow in the cold season.

### 6.7 Ground Failure

Ground failure refers to a variety of processes that can affect the land surface through gravitational movement of unstable geological materials. Some types of ground failure (e.g., land subsidence) involve a slow movement of earth materials, over time scales of days to years; others (e.g., landslides) can occur suddenly and have the potential to produce severe damage and even loss of life. Many types of ground failure are associated with human activity, such as mining, dam construction or roadway development. Indiana has four principal types of ground failure that could affect Indiana residents. These include landslides, fluvial erosion, liquefaction, and ground subsidence, which includes both naturally occurring processes such as karst sinkholes and human-induced processes such as a collapse of underground coal mines. Soil liquefaction, a particular type of ground failure associated with earthquakes, is discussed in Section 6.3.2.2.3.
6.7.1 Landslides

Landslides are a serious geologic hazard common to almost every state in the US. It is estimated that they cause up to $2 billion in damages and from 25 to 50 deaths annually in the U.S. Globally, landslides cause billions of dollars in damage and thousands of deaths and injuries each year.

The term landslide is a general designation for the downslope movement of earth material, due to the effects of gravity. This material can move as a somewhat coherent mass or may be broken up into poorly consolidated soils or rock fragments. Landslides are classified by the type of material in which they occur as well as the type of movement that occurs (Varnes, 1978). As a result, there can be many different types of landslides with highly variable effects on the surrounding area. Figure 140 shows several of the most common types of landslides that can occur. Table 50 summarizes the types of landslides that can occur as a combination of different types of material and types of movement.

Some landslides move slowly and cause damage gradually, whereas others move so rapidly that they can destroy property and take lives suddenly and unexpectedly. A particularly important variable affecting ground movement is the presence of water, which significantly affects the type and behavior of landslide activity. Gravity is the force driving landslide movement, but usually, some external trigger is required to initiate landslide activity. The main causes of landslides include:

- Ground vibration (e.g., earthquakes, blasting activity)
- Failure of slopes due to downward movement (caused by gravity)
- Changes in the water table or surface water (often caused by heavy rains)
- Weakened geologic material due to weathering
- Removal of vegetation due to fire
- Human causes such as excavation or loading of slopes, deforestation/removal of vegetation, mining, or irrigation
- Erosion by rivers causing oversteepening of river banks

Whether or not a landslide occurs typically depends on (1) the degree to which the area is naturally susceptible to landslide activity, and (2) the presence of a process (natural or human-influenced) that triggers the landslide activity. A few key factors determine how susceptible an area is to landslide activity:

- How steep the slopes in the area are (steeper slopes are most vulnerable to landslides)
- How strong the Earth material is (unconsolidated soils or material that is heavily weathered is much weaker than solid bedrock)
- The presence or absence of vegetation (areas with strong root mass to hold sediment in place are less susceptible to landslides)

There are a number of natural forces that can trigger landslides. These include large amounts of rainfall over very short time periods, or steady rainfall over long time periods, which both increase the weight of slopes and can lubricate planes of weakness within rock or sediment. Snowmelt can also trigger landslide activity. Earthquake shaking will loosen the material and cause weak material to move downslope.

Source: USGS Fact Sheet 2004-3072, “Landslide Types and Processes”

A nationwide survey produced by the USGS in 1982 (Radbruch-Hall et al., 1982) assessed the areas of the United States that are susceptible to landslides, and summarized the sites where landslides have occurred across the country. Figure 141, modified from their study, shows the estimated landslide susceptibility and historical occurrence (incidence) of landslides in and around the state of Indiana. The map shows areas of moderate landslide susceptibility in the northwestern and south-central portions of
the state. The southeastern portion of Indiana has a large area of high landslide susceptibility and incidence (shown in dark red), indicating that a high number of landslides have occurred in this portion of the state in the past—and that significant hazard exists for future landslides in that area.

A study conducted by the Joint Transportation Research Center (Deschamps & Lange, 1999) documented the history of earthquakes in the state through much of the 20th century. The map of landslide occurrence in the state (Figure 142) confirms the general patterns of landslide susceptibility shown in Figure 141. Most historical landslides have been concentrated in the areas of high relief in south-central and southeastern Indiana. There is also a significant correlation with bedrock type, as the highest density of landslide occurrence is associated with the Buffalo Wallow and Kope formations, dominated by fine-grained shale, mudstone, and siltstone.

A more recent compilation of detailed records of landslides since 2017 that have affected Indiana roadways is shown in Figure 144. As shown in this map, the majority of the most recent landslide events have occurred in the southeastern part of the state, including areas of Dearborn, Ohio, and Switzerland counties. Neighboring areas of southwestern Ohio (Cincinnati area) and north-central Kentucky are also highly susceptible to landslide damage. The area is particularly susceptible due to the combination of steep slopes near the Ohio River and its tributaries and exposures of weak shale bedrock of the Kope Formation (Potter et al., 2013). The distribution of the Kope formation is shown in Figure 143.

Landslides can impact human-made structures such as bridges, roads, pipelines, dams, and railroads, as well as buildings. They can also impact an area by (temporarily) damming rivers and subsequently cause flooding of large areas.

Areas around Lake Michigan and in the southern portion of the state are at higher risk of landslides. However, the area in the southeastern tip of the state is at greatest risk. Over 1,500 essential and state-owned facilities are located in areas of at least moderate susceptibility and low incidence of landslides. Of those, 52 essential and no state-owned facilities are in areas of high landslide incidence. These 52 facilities are listed in Table 51.

Figure 141. Indiana Landslide Susceptibility and Incidence
Figure 142. Occurrence of Known Landslides
Preventive and remedial mitigation measures include modifying the landscape of a slope to reduce erosion and increase stability, controlling the groundwater and draining water when necessary, constructing tie backs, spreading rock nets, using landslide hazard estimates in developing land use regulations, building retaining walls at the toes of areas likely to landslide, removing mass from the top of slopes, etc. (Highland & Bobrowsky, 2008) The expansion of urban and recreational development into hillside areas has resulted in an increasing number of properties subject to damage as a result of landslides. Landslides commonly occur in connection with other major natural disasters such as earthquakes, wildfires, and floods.

*Figure 143. Exposures of Kope (Shale) Formation in the Cincinnati Area (Potter et al., 2013)*

Shaded area indicates exposure of the Kope formation (siltstone, shale, and mudstone) along the Ohio River and its tributaries. The Kope Formation is highly susceptible to landslide activity.
Figure 144. INDOT Landslides Along Roadways in SE Indiana
Over the years, a number of landslide locations have been mitigated. One such site was in Newburgh, IN where a landslide was causing structural damage to utility power lines, a gas line, and a wooden fence. The landslide was within a few feet of a small historic wooden cabin. In 2011, the FEMA Public Assistance Program funded a project to remove, repair, and replace sidewalks, a handicap ramp, terraced stairs, and asphalt pavement that reduced the risk of future landslides. There were also surface drainage improvements near the buildings and on the slope to catch surface water and divert to an underground drainage tile.

*Figure 145. Newburgh Landslide Prior to Mitigation*
6.7.2 Karst

Southern Indiana has a network of underground caves formed by the natural physical interaction of groundwater with its bedrock, forming what is known as a karst landscape. According to the Indiana Geological & Water Survey, karst topography is a distinctive type of landscape largely shaped by the dissolving action of groundwater, which is naturally slightly acidic, on carbonate bedrock, which in this area is mostly limestone. This geological process, which takes thousands of years, is characterized by unique features such as sinkholes, fissures, caves, disappearing streams, springs, rolling topography, and underground drainage systems. This process typically erodes material in the subsurface, resulting in caves and open space underground; these features have the potential to collapse under the weight of the ground above them, creating a sinkhole. Ground failure of this nature is known as land subsidence. Any structures built above a karst formation could potentially be subject to land subsidence and collapse into a resulting sinkhole. Figure 147 shows the density of karst sinkholes in southern Indiana. The possibility of sinkhole formation is dependent on the physical characteristics of the geology and hydrology of an area. A 2015 study by the Indiana Geological & Water Survey determined the probability of sinkhole formation throughout southern Indiana. Their analysis is based on the density of known sinkholes, as well as a number of geologic, topographic, and hydrologic variables that indicate the future vulnerability to sinkhole formation.

Figure 148 shows the results of this study, showing that areas with the highest probability of sinkhole development generally occur throughout central southern Indiana, with less chance of sinkhole occurrence toward the eastern and western parts of southern Indiana (Letsinger, 2011). This process may occur multiple times in a given area, as the interaction between groundwater and bedrock continues to weaken the subsurface and remove additional material. Additional subsidence may then occur over time in areas with known sinkholes.
Figure 147. Indiana Sinkhole Density (data from IndianaMap)
Figure 148. Risk of Sinkhole Development in Southern Indiana (data from Letsinger, 2011)
Figure 149. State & Essential Facilities in High and Extremely High Sinkhole Development Risk Areas
There are 389 state-owned and essential facilities located in areas of high and extremely high risk of sinkhole development. These include six INDOT facilities, 55 IDNR facilities, 100 schools, 20 police stations, 62 fire stations, 8 emergency operations centers, and 138 care facilities. These are displayed on Figure 149.

### 6.7.3 Underground Coal Mines

Indiana has networks of underground coal mines scattered throughout southern Indiana. Mine subsidence is a vertical ground movement caused by man-made underground mines. These coal mines can fail and create ground failures damaging anything on the overlying surfaces. Mine entrances may be classified as slopes (horizontal entrance) or hoists (vertical entrance). Most mine openings have been permanently sealed and present no danger. However, many openings were sealed improperly and present the risk of sudden collapse or deterioration of the fill material. Currently there is no way to know when or where mine subsidence will occur. Figure 150 maps known coal mine locations by type of entrance.

The southwestern portion of the state is at greatest risk for ground failure due to mine subsidence. Sixty-one essential and state-owned facilities were found to be within areas identified as actively migrating stream corridors. These are mapped in Figure 151 and listed in Table 52.

Figure 150. Indiana Coal Mines (data from IndianaMap)
Figure 151. State & Essential Facilities above Underground Coal Mines
6.7.4 Fluvial Erosion Hazard (FEH)

Fluvial erosion is defined as the erosion caused by the channel migration of streams, rivers, creeks, and other flowing bodies of water.

Removing homes or restricting property development in the floodway, floodway fringe, or fluvial erosion hazard zone, thereby creating in perpetuity, green spaces, parks, golf courses, and other unobstructed land are prime examples of the state's current mitigation efforts to combat the pressures of development of floodways.

FEH has been of particular focus in recent years in Indiana and has resulted in the development of a number of reports. In 2013, the USGS published a report document channel-migration rates of selected streams in Indiana (Robinson, 2013). More recently, in 2017, the USGS published another report addressing vulnerable transportation and utility assets near actively migrating streams in the state (Sperl, 2017). Meanwhile, the Indiana Silver Jackets are supporting a program to identify mitigation resources for individuals and communities wanted to adopt FEH-avoidance strategies. Funding for this project has been provided by the Indiana Office of Community and Rural Affairs (OCRA). The Indiana Fluvial Erosion Hazard Program website (http://feh.iupui.edu) provides a link to an interactive map of major streams and rivers in Indiana that are more susceptible to being impacted by fluvial erosion (https://indnr.maps.arcgis.com/apps/webappviewer/index.html?id=43e7b307a0184c7c851b5068941e2e23). Figure 152 and Figure 153 show examples of erosion in the state while Figure 154 shows the location of actively migrating and relatively stationary streams in Indiana.

Forty-five essential and state-owned facilities were found to be within areas identified as actively migrating stream corridors. These are mapped in Figure 155 and listed in Table 53.

</table>
While Indiana’s FEH program has been going on for several years, the state is currently seeking additional funds in order to identify and mitigate at-risk infrastructure. Meanwhile, numerous counties are starting to use the FEH zone in their planning and zoning, considering them to be areas of avoidance and areas that should be avoided for a planned expansion.

*Figure 152. Fluvial Erosion Example (from [http://feh.iupui.edu/](http://feh.iupui.edu/))*
In 2016, a FEMA Risk MAP mitigation grant funded a system assessment of the White Lick Creek, a major tributary to the West Fork White River (Christopher B. Burke Engineering, LLC, 2016). The stream originates in Boone County and flows through Hendricks and Morgan counties. Multiple recommendations resulted from the study, including passive mitigation strategies for reducing fluvial and flooding risk, site-specific mitigation of fluvial and flooding risk, and system monitoring and adaptive management.

Figure 155. State & Essential Facilities in Actively Migrating Stream Corridors
6.8 Wildfire

The hazard extent of wildfires is greatest in the heavily forested areas of southern Indiana. The IDNR is responsible for almost 1 million acres, of which approximately 411,000 are state-owned forestry, fish & wildlife, state parks, nature preserves, and outdoor recreation. Indiana’s wildfire seasons occur primarily in the spring—when the leaf litter on the ground dries out and before young herbaceous plants start to grow and cover the ground (green up)—and in the fall—after the leaves come down and before they are wetted down by the first heavy snow. During these times, especially when weather conditions are warm, windy, and with low humidity, cured vegetation is particularly susceptible to burning. When combined, fuel, weather, and topography, present an unpredictable danger to unwary civilians and firefighters in the path of a wildfire. Human action can not only intervene to stop the spread of wildfires, but can also mitigate their onset and effects. Forest and grassland areas can be cleared of dry fuel to prevent fires from starting and can be burned proactively to prevent uncontrolled burning.

Indiana Code 14-23-5-1, Establishment of Firefighting Organization, states:

The department, acting through the director and the state forester, shall establish and equip a firefighting organization within the division of forestry for the purpose of detecting, preventing, fighting, and controlling fires in state forest land. The department may extend the same fire detection, prevention, fighting, and control services established to other state land under the department's supervision and control. The department may also establish the same services for land not owned by the state and not lying within a city or town for the purpose of protecting the forests, fields, and grassland of the state.

IDNR is concerned with Wildland Urban Interface wherever the topography and forest land align with houses and communities. Two examples include Brown County in the Nashville area and Ogden Dunes in the northwestern part of the state. Indiana has experienced several wildfires over the years throughout the state that have cause loss of structures and homes.

6.8.1 Historical Occurrences

On October 26, 1952, at 1:15 PM, a fire was accidently started when a homeowner improperly disposed of hot ashes from his wood stove into a nearby field just east of the community of Bartlettsville, IN, in northeastern Lawrence County. The fire danger at the time was said to have been “past the extreme stage”, with the humidity lower than had ever been previously recorded to date. The fire burned until November 3, when rainfall helped to control the fire. This fire alone burned approximately 4,000 acres. Adding in several other smaller fires in the area at this same time, an estimated 6,200 acres were burned during this time period.

On November 10, 1964, at 2:18 PM, a wildfire was spotted in the Hoosier National Forest in southwestern Lawrence County, IN. The fire was reported by Clarisse Carroll, who was stationed in a nearby fire lookout tower (Georgia Tower) at the time. During this period of time, Lawrence County was experiencing record drought conditions and had not seen rain in days. By 4:00 PM that afternoon, the fire was under control with the exception of a small parcel of private land that firefighters were told they could not gain access to. By the next morning, with winds gusting up to 35 mph, the fire was again out of control. After an additional four days of battling, the fire was considered controlled, with patrols
taking place until there was adequate rainfall. An estimated 2,500 acres were burned, with the initial cause of the fire remaining unknown.

In the northwest part of the state, the Indiana Dunes National Lakeshore experiences, on average, 20 to 30 wildland fires in the park each year. Park fire management staff work closely with the 13 local fire departments in the event of a wildfire.

6.8.2 Vulnerability Assessment

The heavily forested areas of southern Indiana as well as Ogden Dunes in northwestern Indiana are at greatest risk of wildfire.

The USDA National Agricultural Statistics Service (NASS) released a Cropland Data layer in 2016 with a ground resolution of 30 meters. Using this dataset, Figure 156 displays those state-owned and essential facilities that are located in areas identified deciduous forest, evergreen forest, or mixed forest. Eleven INDOT, 317 IDNR facilities, 20 schools, 5 police stations, one fire station, and 53 care facilities were found to match those criteria. These facilities may be at greater risk in the event of a wildfire.

6.8.3 Probability of Future Occurrences

The probability of future wildfires will be low for the whole state, meaning it is likely to occur within the next ten years. However, the probability for the Hoosier National Forest and Indiana Dunes National Lakeshore is high, meaning it is probable to occur within the next year.

The probability of future wildfires is directly related to the extreme heat and drought vulnerabilities. According to the NCDC, since the last plan update, the state has experienced significant heat events in 2015, 2017, and 2018. The latest recorded drought was in November 2016, affecting the southern Indiana counties of Pike, Spencer, Vanderburgh, Warrick, Gibson, and Posey. Its drought category was at most a D1. Global climate change may have an impact on the probability of future events; however, it is unclear as to the extent of this impact. While current predictions indicate higher temperatures and an increase in extremely hot days, they also indicate wetter conditions.
Figure 156. State-Owned Facilities Located in Forested Land
6.9  Disease Outbreak

The CDC characterizes a disease outbreak as a sharp increase in the number of incidences of a disease in the population. When the expected or routine amount of incidences of a disease rapidly grows into a public health threat, public health and emergency management officials and medical care professionals must act swiftly to limit morbidity and mortality. The CDC requires state and local health departments to report 75 different types of infectious diseases along with foodborne and waterborne disease outbreaks. Transmission of infectious diseases may occur through a variety of pathways, including airborne inhalation, food, liquids, bodily fluids, contaminated objects, ingestion, or vector-borne spread. Disease outbreaks pose a particular risk to urban and suburban communities due to the close environments in which people interact.

6.9.1  Historical Occurrences

Since November 2017, the Indiana State Department of Health (ISDH) has been investigating an outbreak of acute hepatitis A virus (HAV). In previous years, Indiana had an average cases of 20 HAV per 12-month period. Since the outbreak and as of February 8, 2019, the state has seen 989 cases resulting in 499 hospitalizations and 2 deaths. Over 117,000 vaccines have been administered since January 1, 2018.

On Friday December 11, 2015, a staff member at an elementary school in Allen County was diagnosed with meningococcal disease (meningitis). The Fort Wayne-Allen County Department of Health (DOH), ISDH, and the CDC worked together and decided to offer preventative antibiotics to all students and faculty of the school. On Tuesday December 15, 2015, 449 people were provided with preventative antibiotics. School nurses and volunteers weighed all children to determine the appropriate dosage.

The Disease Reporting and Control Rule requires health care providers, hospitals, and laboratories to report communicable diseases and conditions. The Indiana State Department of Health Epidemiology Resource Center publishes an annual report of infectious diseases documented in the state and their incidence. Recent reports can be found at https://www.in.gov/isdh/20667.htm.

6.9.2  Probability of Future Occurrences

The 2018 IN CCIA predicts a rise in temperature and fewer extremely cold temperature days. As a result, more pests may survive winter, leading to a potential increase in cases of the West Nile virus, the Zika virus, and Lyme disease. According to the report “Traps in Marion County already show a 500% increase in the number of mosquitoes from 1981 to 2016” (Widhelm, et al., 2018).
7 Technological Hazards

“Technological hazards can affect localized or widespread areas, are frequently unpredictable, can cause property damage and loss of life, and can significantly affect infrastructure in many areas of the United States. FEMA recognizes that a comprehensive strategy to mitigate the nation’s hazards cannot address natural hazards alone.”(https://www.fema.gov/media-library-data/20130726-1545-20490-2423/mhira_te.pdf). This section of the plan will discuss the following technological hazards:

- **Dam and levee failures** - collapses or failures of impoundment structures that cause downstream flooding
- **Low head dams** - A low head dam is a manmade structure spanning a river or stream channel from bank to bank in which water flows over the entire length of the top of the dam which may produce strong turbulent and recirculating currents at the base.
- **Hazardous materials release** - uncontrolled releases of hazardous materials from fixed sites or during transport
- **Structural fire** - uncontrolled burning in residential, commercial, industrial or other properties in rural or developed areas (not forest and wildfires)
- **Communication system failure** - communications failures are sometimes a consequence of disasters such as hurricane-force winds, floodwaters, and seismic activity resulting in damage to communication equipment
- **Public utility failure** – Similar to communication system failures, public utilities located in vulnerable areas can be impacted by disasters
- **Air transportation incidents** - Aircraft accidents can occur for a variety of reasons, including mechanical failure, poor weather conditions, human error, and intentional causes.

7.1 Dam and Levee Failure

Dams are structures that retain or detain water behind a large barrier. When full, or partially full, the difference in elevation between the water above and below the dam creates large amounts of energy, creating the potential for failure. The same potential exists for levees when they serve their purpose, which is to confine flood waters within the channel area of a river and exclude that water from land or communities land-ward of the levee. Dams and levees can fail due to 1) water heights or flows above the capacity for which the structure was designed or 2) deficiencies in the structure such that it cannot hold back the potential energy of the water. If a dam or levee fails, issues of primary concern include loss of human life/injury, downstream property damage, lifeline disruption (of concern would be transportation routes and utility lines required to maintain or protect life), and environmental damage.

Many communities view both dams and levees as permanent and infinitely safe structures. This sense of security may well be false, leading to significantly increased risks. Both downstream of dams and on floodplains protected by levees, a false sense of security often leads to new construction, added infrastructure, and increased population in at risk areas over time. Levees in particular are built to hold back flood waters only up to some maximum level, often the 100-year (1% annual probability) flood event. When the maximum is exceeded by more than the design safety margin, the levee will be overtopped or otherwise fail, inundating communities in the land previously protected by that levee. It
has been suggested that climate change, land-use shifts, and some forms of river engineering may be increasing the magnitude of large floods and the frequency of levee failure situations.

In addition to failure that results from extreme floods above the design capacity, levees and dams can fail due to structural deficiencies. Both dams and levees require constant monitoring and regular maintenance to assure their integrity. IDNR has created the Indiana Dam Safety Inspection Manual, which can be found at [https://secure.in.gov/dnr/water/3593.htm](https://secure.in.gov/dnr/water/3593.htm). The regulation of dams in Indiana is addressed under Indiana Code: IC 14-27-7.5 Regulation of Dams, and 312 IAC Article 10.5 Regulation of Dams. Many structures across the US have been under-funded or otherwise neglected, leading to the recognition that certain structures are unsafe or, rarely, can lead to actual failure. The threat of dam or levee failure may require substantial commitment of time, personnel, and resources. Since dams and levees deteriorate with age, minor issues become larger compounding problems, and the risk of failure increases. Additionally, levees prohibit the natural dissemination and storage of flood waters resulting in more water being forced downstream than would otherwise be the case.

The IDNR Division of Water assigns the hazard potential for dams and levees based on the federal classification system. Table 54 below describes each hazard classification.

### Table 54. Hazard Potential Classification System for Dams

<table>

<td>Significant</td>
<td>No probable loss of human life but can cause economic loss, environmental damage, disruption of lifeline facilities, or can impact other concerns. Significant hazard potential classification dams are often located in predominantly rural or agricultural areas but could be located in areas with population and significant infrastructure.</td>
</tr>
<tr>
<td>Low</td>
<td>No probable loss of human life and low economic and/or environmental losses. Losses are principally limited to the owner’s property.</td>
</tr>
</tbody>
</table>

Both population and infrastructure located downstream are at risk in the event of a dam or levee failure. Developing an Incident and Emergency Action Plan (IEAP) and updated inundation maps is the first step toward highlighting the areas of greatest vulnerability in each community. Figure 157 shows the locations of all dams in Indiana, Figure 158 shows state-regulated dams in Indiana, symbolized by their federal hazard classification, and Figure 159 shows the locations and density of high hazard dams in Indiana. The state has 243 high hazard dams, 128 of which have an IEAP. These dams are listed in Appendix C. The southern part of the state, especially in and around Brown County, has the highest concentration of high hazard dams.

Starting in 2015, IDHS began a partnership with IDNR and OCRA to fund and develop 29 IEAPs for communities throughout the state.

The following table lists dam failures that have occurred in Indiana since 2014.

The Indianapolis North Flood Damage Reduction Project, once completed, will protect more than 1,000 homes in the Warfleigh, Broad Ripple, and Butler-Tarkington neighborhoods, including much of the of the Butler University campus, from damage in the case of a 300-year flood event.

The U.S. Army Corps of Engineers is constructing this project in coordination with the City of Indianapolis Department of Public Works.

All phases of the project will be built and maintained to qualify the project for FEMA accreditation, a process which should redraw the floodplain and reduce flood insurance rates for many residents.
Figure 157. All Dams

Disclaimer: Information on dams not regulated by the State of Indiana may be extremely limited and/or inaccurate and should only be considered following field verification by the user. Hundreds of other dams, either not regulated by the State of Indiana or reported to IDNR, exist within Indiana and are not listed in the index or reflected on this map.
Figure 158. State-Regulated Dams
Figure 159. State-Regulated High Hazard Dams
7.1.1 Low-Head Dams

Low-head dams were first built in Indiana in the 1800s to provide energy for milling, power generation, and water diversion. Over time, many of these dams were damaged or abandoned and left in rivers. Low-head dams obstruct the general flow of water in rivers and span from bank to bank. As of 2018, 164 low-head dams were known to remain in Indiana Waterways (see Figure 160). The number of low-head dams fluctuates as they are discovered and/or removed. These dams pose a great risk to water enthusiasts due to many being in disrepair and the hydraulic churning motion that takes place as the water velocity drives the water to the river bottom and recirculates the highly aeriated water back to the surface. This churning action, much like a washing machine, traps debris, boats and people who mistakenly get too close to the structures and are pulled to the face of the dam. In Indiana, from May 1997 through October 2018, 27 people have lost their lives at low-head dams and 86 have been rescued, with at least 23 sustaining injuries.

Thanks to a grant IDHS received in 2015 to conduct education and outreach activities on the risks and hazards of low-head dams, a number of activities have taken place. These include the development of a 30-minute documentary, a 14-minute youth-oriented program, and a 1-minute social media piece; a one-day low-head dam symposium attended by over 300 people; an inventory of low-head dams; the development of a web-based interactive map (https://indnr.maps.arcgis.com/apps/webappview/index.html?id=729f94f7963a42d9ab0d38c639590f ea); and the development of an outreach campaign.

“Over, Under Gone – The Killer in Our Rivers” documentary received the National Association of State Dam Safety Officials Midwest Region Award of Merit in 2017. The documentary is available online at https://www.wfyi.org/programs/over-under-gone/television/over-under-gone-the-killer-in-our-rivers.

Indiana Silver Jackets team members have developed artwork for a low-head dams warning sign that both verbally and visually warns people of the hazard and utilizes color schemes and word choices similar to workplace warning signs. 37 such signs were placed upstream and downstream of the 3 low-head dams in the Fort Wayne area and Citizens Energy has deployed smaller signs near dams where the public can walk near their low-head dam structures. Team members have presented at both statewide and national conferences including INAFSM, Association of State Dam Safety Officials (ASDSO), Boat Sport and Travel Show, Stay Afloat Biannual Conference, etc. encouraging public education (https://www.in.gov/dnr/outdoor/9419.htm) and the development of local champions to help educate and encourage the removal or modification of low-head dam structures. A student curriculum has been developed to teach students about low-head dams. The curriculum is currently being beta tested with a few select teachers. The goal is to provide the board of education compliant curriculum, and all the teaching materials to local schools, scouting groups and agricultural youth organizations so they can spread the message. Most recently, team members have been working with IDEM and the United States Army Corps of Engineers (USACE) to develop a set of guidelines to assist dam owners navigate the environmental testing and permitting processes for dam removals.
Pete Cinotto, a USGS Silver Jackets team member, developed a prototype app that locates known low-head dams within 12 miles of a user and warns the user when approaching a dam. The app links to DNR’s online inventory.

7.1.2 Non-Levee Embankments

Along with accredited levees regulated by federal agencies, there are also what are referred to as Non-Levee Embankments (NLE), which typically parallel the direction of natural flow. An embankment is an artificial mound of soil or broken rock that supports railroads, highways, airfields, and large industrial sites in low areas, or impounds water. NLEs are often highways or railroads built on fill in low lying areas and thus tend to impose lateral constraints on flood flows, and typically contain the following characteristics:

- They are elevated linear features adjacent to waterways and within the floodplain.
- They are typically man-made and include agricultural embankments built by landowners and road and railroad embankments banks.
- They are levee-like structures, but are not certified or engineered to provide flood protection.

The National Committee on Levee Safety estimates that the location and reliability status of 85% of the nation’s NLEs are unknown. In Indiana, the majority of NLEs are unidentified and are typically not maintained. NLEs impose lateral constraints on flood flows, reducing the floodplain storage capacity and increasing the flood velocity. As a result, downstream flooding and the potential for stream erosion can increase. As such, NLEs can give a false sense of security and protection to the people residing near NLEs. For these reasons, it is extremely important to map where these features are located.

Living with levees is a shared responsibility. While operating and maintaining levee systems are the levee sponsor responsibility, local officials are adopting protocols and procedures for ensuring public safety and participation in the NFIP.

7.2 Hazardous Materials Release

Hazardous materials are any solid, liquid, or gas that can pose a threat to human health and/or the environment due to being radioactive, flammable, explosive, toxic, corrosive, a biohazard, an oxidizer, an asphyxiant, or capable of causing severe allergic reactions. Hazardous materials are most often released as a result of accidents during transportation or at fixed facilities.

The transportation of chemicals and substances along interstate routes and railroads is commonplace in Indiana. The rural areas of Indiana have considerable agricultural commerce, creating a demand for fertilizers, herbicides, and pesticides to be transported along rural roads. Also, Indiana is bordered by the Ohio River to the south. Barges transport chemicals and substances along these waterways daily. These factors increase the chance of hazardous material releases and spills throughout the State of Indiana.

The release or spill of certain substances can cause an explosion. Explosions result from the ignition of volatile products such as petroleum products, natural and other flammable gases, hazardous materials/chemicals, dust, and bombs. An explosion potentially can cause death, injury, and property damage. In addition, a fire routinely follows an explosion, which may cause further damage and inhibit emergency response. The release of hazardous materials can also lead to property damage, short and long term health effects, serious injuries, and even death. Emergency response to incidents involving the release of hazardous materials may require fire, safety/law enforcement, search and rescue, and hazardous materials units.

The emergency personnel assigned to IDHS’s Division of Fire and Building Safety serve as on-site technical advisors at large fires and hazardous materials incidents to the more than 900 fire departments within the state. They respond to a wide range of emergencies, often working side by side with other state agencies, such as the Indiana State Police, IDEM, and state and local health departments. When an incident becomes so involved or so large that local resources are taxed beyond their capabilities, the emergency responders often assist these jurisdictions by identifying and placing in action the appropriate state resource.

IDEM’s Office of Land Quality’s Emergency Response program responds to incidents involving spills to soil or waters of the state. Responders in IDEM’s four regional offices work closely with local, federal, and other state responders to protect Indiana’s environmental resources.

Environmental emergencies can be reported by calling IDEM’s 24-hour Emergency Spill Line at 1.888.233.7745 or 1.317.233.7745. The Office of Land Quality’s emergency responders are available any time to receive spill reports and provide response assistance.

Indiana Code requires any shipment of low-level radioactive waste, high-level radioactive waste, spent nuclear fuel, and/or Highway Route Control Quantity radioactive material be permitted before traveling in Indiana. An online application is available for low-level radioactive waste.
7.3 Structural Fire

Structural fires are uncontrolled fires in populated areas that threaten life and property. Structural fires have many causes, including smoking, arson, industrial accidents, electrical malfunctions, damage to utility lines, laboratory accidents, lightning, and explosive or combustible materials.

Structural fires occur in virtually every community and are the most common hazard facing most communities in Indiana and across the country.

According to the U.S. Fire Administration, there were 2.8 deaths and 8.6 injuries per 1,000 fires in 2016 in Indiana. For residential structure fires, the numbers were higher at 7.8 deaths and 25.2 injuries per 1,000 fires. These numbers are higher than the national average. Structural fires accounted for 80% of fire-related deaths and 86.2% of fire-related injuries. Residential fires accounted for the majority of structural fire deaths and injuries. The relative risk of dying in a fire in 2016 was slightly higher in Indiana (1.1) than the average relative risk for the country (1.0).

On December 18, 1964, a nursing home in Fountaintown, IN was engulfed with flames. The home was once a 15-room mansion that was converted into a private convalescent center in 1946. There were 34 patients that lived in the home at the time of the fire, and 20 patients lost their lives. The fire started at 2:30 A.M. in the basement where the furnace overheated and ignited a wall while the temperature outside was four degrees above zero. There was no hydrant system nearby, therefore the firemen had to use tanker trucks to fight the fire. They also broke through the ice on nearby Brandywine Creek to get water for the fire.

On January 11, 2004, a major structural fire swept through the historical district of Jeffersonville, IN. Winds gusted at 20-30 mph at the time of the blaze, which made it difficult for firefighters to combat. The fire started in an electrical junction box in the first floor ceiling of the Horner Novelty Company on Spring Street. This was a two-story building occupying around 40,000 square feet of the district. Seven area mutual aid engines were called in to assist, including assistance from Kentucky. These mutual aid engines included over 100 firefighters on scene. In total, seven commercial buildings, one apartment building, one residential structure, and three garages were completely destroyed, with damages exceeding $7,000,000.

7.4 Communications System Failure

Communications failure can include telecommunications failure, radio communications failure, and information technology (IT) failure.

7.4.1 Telecommunications Failure

Telecommunications assets consist of any electronic device—operated by a privately- or publicly-owned entity—used for the purposes of message delivery.

Telecommunications failure may have a significant impact on a community since nearly every aspect of modern life is dependent on digital infrastructure. Economic and national security, as well as emergency response and recovery, relies on the assets and operations of telecommunications infrastructure. Disruption to telecommunications systems, whether as a result of terrorist or other malicious attacks,
natural disasters, or human failure to adhere to best practices, can lead to technological and financial losses, or even loss of life.

### 7.4.2 Radio Communications Failure

Radio communication failure is the severe interruption or loss of private and/or public radio communications systems. The disruption may be caused by equipment failure, deliberate or unintentional human acts, or as a result of a natural, technological, or human-induced disaster. The most common associated problems can range from minor, for example, brief public inconvenience, to severe losses of production and revenues for businesses and institutions and command and control at the government level.

### 7.4.3 Information Technology Failure

Information technology (IT) infrastructure consists of all state government computers and servers, as well as Ethernet and Internet connectivity. The Indiana Office of Technology (IOT) manages IT operations for all state facilities, providing tools and services to support the regulatory, administrative, and daily operations of the state, including high-speed network with wireless access, central web hosting, free and low-cost software for individual use, tools and support for instruction and research, and supercomputers for data analysis and visualization.

An IT infrastructure failure may consist of a localized, statewide, or nationwide disruption of the hardware, programs, Ethernet, and/or Internet. Failure of any one of these elements can impact the entire IT system. Failure can result from the following exposures:

- **Physical**: consists of possible physical damage to server equipment and critical hardware caused by either natural hazards or intentional destruction
- **Capacity**: consists of possible overload of available resources resulting in services slowing or shutting down
- **External**: consists of an attack of the university network from either an external IP address or a computer with direct network access. External attacks undermine the confidentiality, integrity, and/or availability of hardware and the information on it.

### 7.5 Public Utility Failure

Public utility failure refers to short- or long-term disruptions to electrical power, water, and/or gas. There are two types of electrical failures: brownouts and blackouts. Brownouts occur when there is a brief drop in voltage due to excessive demand for power (e.g. during heat waves). Brownouts may last for a few minutes or few hours and cause lights to dim, appliance motors to slow, equipment to reset, and less heat/air to be generated. Blackouts occur when there is widespread loss of power as a result of a natural hazard, equipment failure, sabotage, or accident.

In the event of an electrical failure, numerous community functions may be affected, including information technology, communication, and emergency services. Additionally, public buildings could lose climate control, posing health risks during extreme heat or cold.

Water failure occurring from water pipe breaks can result in flood damage to buildings and infrastructure. Additionally, the loss of water usage may occur due to contamination of the water.
supply. Prolonged water failure can prevent or hinder daily operations and could affect the health and safety of the population.

Gas failure occurs as a result of a broken valve or ruptured pipeline and typically results in the release of natural gas into the environment or structure. The release of natural gas can ignite a fire or explosion, and prolonged exposure can lead to serious health risks, including loss of consciousness or death.

On October 31, 1963, a propane leak at a concession stand at the Indiana State Fairgrounds Coliseum led to a massive explosion during a “Holiday on Ice” show. Out of the more than 4000 spectators, 81 died and nearly 400 were injured. The Ohio State University’s Disaster Research Center wrote a detailed report, “Disaster in Aisle 13” for the Office of Civil Defense. This report documents not only the events of the disaster, but also the organizational changes that occurred within the next year. These include the creation of a Safety Director position and the development of an inter-hospital radio-telephone system.

On April 6, 1968, two explosions occurred at the Marting Arms Sporting Goods Store in downtown Richmond, killing 41 people and injuring more than 127. The first explosion led to the second explosion, which ignited gunpowder and primers stored in the basement. The explosion destroyed three buildings, twenty nearby buildings were condemned, and 125 were damaged. The total estimated dollar loss was $15 million (over $100 million dollars today). Fire departments from Wayne County, neighboring counties and Ohio assisted.

7.6 Air Transportation Incidents

Air transportation is used to carry human passengers, as well as thousands of tons of cargo. Aircraft accidents can occur for a variety of reasons, including mechanical failure, poor weather conditions, human error, and intentional causes. The majority of aircraft accidents take place during take-off or landing and may affect unpopulated, residential, or metropolitan areas. Incidents involving military, commercial, or private aircraft can also occur while the aircraft is on the ground. Aircraft accidents can lead to incidents of significant property damage, environmental damage, fire, explosion, hazardous material release, serious injuries, and death.

On December 13, 1977, Air Indiana Flight 216 crashed on takeoff at the Evansville Regional Airport as it was headed to Nashville. All 26 passengers and 3 crew perished. The passengers included the University of Evansville basketball team. The National Transportation Safety Board (NTSB) determined that the probable cause of the accident was an attempted takeoff with the rudder and right aileron control locks installed, in combination with a rearward center of gravity due to inappropriately loaded passenger baggage.

On October 31, 1994, American Eagle Flight 4184 headed to Chicago O’Hare from Indianapolis crashed into a field in Roselawn, IN while on a hold pattern in Chicago. All 64 passengers and 4 crew perished. The NTSB determined that the probable causes of the accident were the loss of control, attributed to a sudden and unexpected aileron hinge moment reversal that occurred after a ridge of ice accreted beyond the deice boots.
8 Human Hazards

The SHMP has a stronger focus on the risk assessment and mitigation of natural hazards for many reasons, but primarily because there is better understanding of the return period for most natural hazards. The frequency and potential severity of human hazards is far less predictable. Other planning efforts, including the Indiana THIRA, address the preparedness and response activities related to human hazards.

8.1 Cyberattack

Cyberattacks are malicious attempts to access or damage a computer system (Department of Homeland Security, 2018). Unlike physical attacks which can be immediately responded to, cyberattacks are often difficult to identify and address. Cyberattacks can be in the form of viruses or the introduction of malware which alter or erase programs and systems, accessing and/or altering restricted files or systems, and accessing the computer or device of another person to attack others or steal confidential information. Cyberattacks can have wide-ranging effects on the individual, organizational, community, and national level.

These risks include:

- Organized cybercrime, state-sponsored hackers, and cyber espionage can pose national security risks.
- Transportation, healthcare, power, and other services may be disrupted by large-scale cyber incidents.
- Vulnerability to data breach and loss increases if an organization’s network is compromised. Information about a company, its employees, and its customers can be at risk.
- Unauthorized access to individually-owned devices such as computers, tablets, mobile phones, and gaming systems that connect to the Internet. Personal information may be at risk without proper security.

In February 2018, the Director of National Intelligence, Daniel Coats, identified cyber threats at the top of the list of worldwide threats (Department of Defense, 2018). In 2014, the Federal Bureau of Investigation (FBI) expanded its “Most Wanted” list with a “Cyber Most Wanted” list. As of December 2018, it included 63 individuals or groups. While there were 12 billion records stolen in 2018, it is expected for that number to grow to 33 billion by 2023. Identity theft has affected about 60 million Americans in 2018, compared to 15 million in 2017 (Norton by Symantec, 2018).

The Indiana Information Sharing and Analysis Center (IN-ISAC) offers high-level consulting at no cost to organizations. This consulting is intended to help those with limited or no cybersecurity knowledge or skills in-house, get their questions answered and their security programs started. See https://www.in.gov/cybersecurity/in-isac/3649.htm.
While ransomware has been publicized in the news in recent years, a growing number of attacks were remote code execution attacks associated with cryptomining (Imperva, 2018).

The past few years have seen a number of high-visibility attacks in Indiana. These include attacks on Lutheran Hospital in Fort Wayne (Becker’s Hospital Review, 2018), Hancock Health in Greenfield (IndyStar, 2018), the Indiana Department of Education (IndyStar, 2018), and the Indiana National Guard (WFYI Indianapolis, 2018). The United States is the top target of cyberattacks in the world.

**Figure 163. Attacks by Target Country (Norton)**
Indiana State government systems are not immune. Approximately 41% of the email received is legitimate. Over a 9-month period in 2018, more than 30 million emails and 24,000 viruses were blocked from entering State computer infrastructure. Additionally, over 2 billion connection requests were blocked at the firewall. The most common source of blocked connections came from the Ukraine, followed by Russia and China.

### 8.2 Active Shooter

An active shooter is a person who appears to be actively engaged in killing or attempting to kill people in a populated area — typically employing the use of firearms. In some cases, active shooters use other weapons and/or improvised explosive devices (IED) to cause additional victimization and act as an impediment to law enforcement and emergency services responders. There may be no pattern or method to their selection of victims.

These situations are dynamic and evolve rapidly, demanding immediate deployment of law enforcement resources to stop the shooting and mitigate harm to innocent victims. The average active shooter incident lasts approximately 12 minutes, while 37 percent last less than five minutes. In 57 percent of active shooter incidents, police arrive while the shooting is still underway.

In recent years, the United States has experienced a number of active shooter events on school campuses. According to the Washington Post, 220,000 students have experienced gun violence at school since the Columbine High School shooting in 1999 (The Washington Post, 2019). Indiana has also been affected, including a shooting involving a 13-year-old boy at Noblesville West Middle School on May 25, 2018, that injured a teacher and a student, and a shooting at Dennis Intermediate School in Richmond on December 13, 2018, that resulted in the death of the 14-year-old shooter (IndyStar, 2018).

The Indiana State Police has prepared a number of resources for schools and places of work, worship, and recreation to help the public understand how to respond to an active shooter event. These are available from [https://www.in.gov/isp/3191.htm](https://www.in.gov/isp/3191.htm). The Indiana State Police will do live Active Shooter Event presentations upon request.

Indiana is one of just a handful of states that has a “Red Flag Law”. This law addresses circumstances where it would be appropriate for a police officer to take custody of a citizen’s firearms, by way of a warrant, or immediately when exigent circumstances are present and it can be clearly articulated the safety of the public was in jeopardy. In Indiana, this law is more commonly referred to as the “Jake laird Law”.

Jake Laird was an Indianapolis Metropolitan Police Department (IMPD) officer killed on August 18, 2004 when IMPD responded to numerous 911 calls reporting gunfire in a near south side neighborhood of Indianapolis (Indianapolis Metropolitan Police Department, 2019).
8.3 Arson

Arson is any willful or malicious burning, or attempt to burn—with or without intent to defraud—a dwelling, public building, motor vehicle or aircraft, and/or the personal property of another individual or entity. The FBI reports that in 2017, law enforcement agencies reported 41,171 arsons cases in the nation, representing a rate of 13.2 arson offenses from every 100,000 inhabitants nationwide. Forty-five percent of all arson offenses involved structures (e.g., residential, storage, public, etc.) Mobile property was involved in 24.5 percent of arsons, and other types of property (such as crops, timber, fences, etc.) accounted for 30.5 percent of reported arsons. The average dollar loss per arson incident was $15,573.

The arson rate in Indiana in 2017 was 11.5 incidents per 100,000 people, which was lower than the rate of the United States as a whole. Overall, the arson rate has declined since 2007 (see Figure 164).

Figure 164. Arson Rate from 2007 to 2017

8.4 CBRNE Attack

CBRNE refers to chemical, biological, radiological, nuclear, or explosive attacks. There is a growing threat of terrorism incidents employing biological, chemical, and radiological agents. A biological agent is a naturally occurring substance that can cause harm to living organisms and can be adapted for use as a weapon (i.e., anthrax, cholera, and tularemia.) It is estimated that there are over 1,200 biological agents
that can be found or modified into liquid droplets, aerosols, or dry powders. Chemical agents are primarily produced with the purpose to incapacitate or kill. Chemical agents can be found in liquid, gas, or solid form and are disseminated by using heat to evaporate the agent, exploding munitions, or a mechanical spray device. Radiological agents can be naturally occurring or manmade and may be weaponized using an explosive device. Exposure to radiological agents can cause changes in cell growth and functioning, resulting in significant health issues, or death.

The emergency response staff assigned to the CBRNE section of IDHS are hazardous materials and radiation specialists who have been trained and equipped to assist local jurisdictions with any major incident. Services provided by the CBRNE section are provided at no cost to the requesting agency.

Local, state, or federal emergency response agencies needing emergency assistance from the IDHS CBRNE staff can request this assistance by calling the State of Indiana Emergency Operations Center at 1.800.669.7362 (press 1).

8.4.1 Radiological Emergency Preparedness Program

The IDHS Radiological Emergency Preparedness Program (REP Program) coordinates efforts to protect and respond to incidents involving commercial nuclear power plants. The REP Program provides the State of Indiana and local communities with plans, training and guidance related to nuclear energy incidents. The IDHS REP Program follows federal guidance and policies to ensure capabilities exist to prevent, protect against, mitigate the effects of and respond to and recover from incidents involving nuclear power plants.

Indiana is considered part of the emergency preparedness zones for four commercial nuclear power plants, two in Michigan and two in Illinois (see Figure 165). This is a geographical area surrounding a commercial nuclear power plant for which specialized emergency planning is needed. Indiana is part of the ingestion pathway emergency preparedness zone, which includes a radius of approximately 50 miles from each of the nuclear power plants.

The IDHS REP Program provides training and education regarding nuclear power plants and the ingestion pathway, including the basic effects of radiation, identification of possible preventative protective actions taken for food and water as well as sampling techniques for soil, water and food stuffs. FEMA evaluated exercises for Ingestion Emergency Planning Zone are conducted every eight years.
8.5 Hostage Situation

Hostage situations involve an individual or group being forcefully held by another individual or group as security against an implied threat, or in order to assure that specified terms are met in a conflict. Barricade situations involve an individual or group that have taken position in a physical location, most often a structure or vehicle, and does not allow immediate police access and refuses police orders to exit. Subjects of barricade situations may be known to be armed, thought to be armed, have access to weapons in the location, or be in an unknown weapon status. Hostage and barricade situations may be the result of individual criminal activity, public disturbances, or terrorism.

8.6 Riot

Riots and civil unrest occur when groups or individuals disrupt a community to the degree that intervention is required to protect public safety. They typically occur in more urban areas or where there are dense populations. Common triggers of such events include racial tension, religious conflict, unemployment, and unpopular political actions. In extreme cases, riots and civil unrest can result in injuries, deaths, and property damage. The most common activities associated with this hazard include looting, vandalism, and arson.
8.7 Terrorism

There is no universally accepted definition of terrorism, even among US government agencies. The Code of Federal Regulations (CFR) defines terrorism as “the unlawful use of force and violence against persons or property to intimidate or coerce a government, the civilian population, or any segment thereof, in furtherance of political or social objectives” (28 C.F.R. Section 0.85). Acts of terrorism can occur in many forms, depending on technological means available to the terrorist, the motivation behind the act, the points of weakness of the target, and the terrorist’s ingenuity.

Sabotage is the destruction of property or an obstruction of normal operations in order to defeat, hinder, or subvert a cause or endeavor. Acts of sabotage may be carried out by an individual or group, for the purpose of terrorism or in the course of a public disturbance. Sabotage can take many forms, including: bombings; organized extortion; use of biological, chemical, and radiological agents; pre-meditated plans of attack on institutions of public assembly; information technology disruptions; ethnic/religious/gender intimidation; and disruption of legitimate scientific research or resource-related activities.

8.7.1 Indiana Intelligence Fusion Center

The Indiana Intelligence Fusion Center is a collaborative effort of multiple agencies operated by the Indiana state Police that provides resources, expertise, and information to the Center with the goal of maximizing the ability of local, state, and federal partners to detect, prevent, investigate, and respond to criminal and terrorist activity. The primary product of the Fusion Center is situational awareness provided through notifications, warnings, and alerts supported by law enforcement intelligence derived from the application of the intelligence process. Based on law enforcement’s requirement of actionable intelligence, information is collected, integrated, evaluated, analyzed, disseminated, and maintained.

The core function of the Fusion Center is the Intelligence process, which is the orderly, systematic process by which information is gathered, assessed, and distributed. Regardless if the mission of the Fusion Center is All-Crimes, Terrorism focused, or All-Hazards, regardless if the stakeholders supported are strictly Law Enforcement, Public Health, or Emergency Response, and regardless of the types of information the Fusion Center receives, the intelligence process is means by which raw information becomes a finished intelligence product for use in decision making and action planning.
Mitigation Strategies

In sections 6 and 7 of this plan the risk assessment identified a number of natural, technological and man-made hazards that the State of Indiana experiences. The state planning team members understand that although hazards cannot be eliminated altogether, the state can work with partners towards building a more disaster-resistant state.

Priorities

The planning team ranked priorities based on the desired timeline for completion. The timelines described below are based on funding availability.

- High: desired to be accomplished within the next year
- Medium: desired to be accomplished within the next two to three years
- Low: desired to be accomplished within the next four to five years

Goals & Objectives

The goals and objectives listed below are a valid representation of the long-term and broad visions of the state’s mitigation efforts. The strategies listed in Table 56 are how the state will work towards achieving the goals and objectives listed here.

1. Integrate Indiana’s mitigation policies and programs to maximize efficiency and leverage funding
   a. Ensure better coordination of federal, state and local mitigation activities
   b. Identify new partners to collaborate on the state hazard mitigation planning team
   c. Develop a program of affordable housing that is resilient to flooding
2. Lessen the impacts of disaster to new and existing infrastructure, residents and responders
   a. Encourage the integration of Hazard Mitigation Planning into local Comprehensive Plans
   b. Evaluate and strengthen communication and transportation emergency services
   c. Retrofit critical and essential facilities and structures to withstand disasters
   d. Support compliance with the NFIP
   e. Identify opportunities to reduce repetitive loss and severe repetitive loss incidents
3. Minimize the loss of life and injuries caused by disasters
   a. Develop public awareness and outreach programs
   b. Improve emergency sheltering
4. Promote research education and outreach to expand Indiana’s knowledge about disasters and their impacts
   a. Conduct new studies/research to profile hazards and promote mitigation
   b. Improve education and training of emergency personnel and public officials
   c. Review and update existing, or create new, community plans, maps & ordinances

10 Local Capabilities

10.1 Local Funding and Technical Assistance

IDHS supports the development of local mitigation plans through funding, technical assistance, and expertise. IDHS relies on ongoing partnerships with Indiana Silver Jackets, nonprofit entities, private contractors and academic institutions working with local jurisdictions to support education, outreach, and planning.

An example of strong local capability is within the City of Columbus in Bartholomew County. The Columbus Flood Risk Management Plan was completed in June of 2013 and addresses all aspects of the flooding risk in the community. The plan assesses the threat from local streams, provides the background information for the Flood Response & Evacuation Plan, evaluates opportunities to mitigate flooding risks for specific streets and neighborhoods, and identifies regulatory actions that could prevent the flooding risk from becoming worse. The Columbus Flood Risk Management Plan was recognized with the 2013 Excellence in Floodplain Management award from the Indiana Association for Floodplain and Stormwater Management (INAFSM). The plan is available online at http://www.columbus.in.gov/planning/flood.

Another example of strong local capability is demonstrated by the Town of Spencer and the City of Indianapolis, which both have developed flood response plans that leverage the USGS flood libraries.

Starting in 2016, IDHS worked in partnership with IDNR and OCRA to fund and develop 20 Flood Response Plans for communities throughout the state. These communities are: Alexandria, Anderson, Bloomington, Crawfordsville, Decatur, Edinburgh, Elora, Elwood, Franklin, Greenfield, Lebanon, Martinsville, Nashville, New Castle, Noblesville, Portland, Princeton, Seymour, Vincennes, and Wabash.

One measure of the improved local capabilities is the status of the local planning effort and the ongoing activity to update the plans. In the past five years, 58 of Indiana’s 92 counties have completed a MHMP update and most of the rest are in the process of completing their first five-year update. For 77 of these counties, IDHS partnered with The Polis Center at IUPUI to include Hazus level 2 analyses in their MHMP risk assessments. The level 2 analysis uses the county’s local data to best estimate the potential physical, social, and economic losses of a disaster. These results better inform mitigation and planning strategies.

Local capabilities are enhanced by the Indiana Association of Regional Councils (IARC), a statewide association of regional planning organizations that promotes regional strategies and solutions to address local issues and supports grant writing.

IARC Regions (Figure 166):

12. Southern Indiana Development Commission
13. West Central Indiana Economic Development District
14. North Central Indiana regional Planning Council
15. Eastern Indiana Regional Planning Commission

10.2 Local Plan Integration

The current process of integrating local data and mitigation strategies into statewide planning efforts has been completed on an as-needed basis and as existing resources allow. One of the strategic priorities in 2019-2020 for IDHS is expanding mitigation and resiliency in the State. This increased focus will allow IDHS Mitigation to have a dedicated mitigation planner to perform the initial review of all county plans before submission to FEMA. This dedicated planner will assist the counties by providing technical support, training, and act as a liaison between the counties and subject matter experts. The planner will review local strategies to integrate into the State Multi-Hazard Mitigation Plan, and to generate reports on an as-needed basis. One of the priorities of the IDHS Mitigation program each year is to obtain grant funding to assist local jurisdictions in their planning efforts. All 92 counties have recently received FEMA grant funding to assist them financially in updating their local plans.
Figure 166. IARC Regions
10.3 Process of Prioritizing Local Mitigation

When prioritizing local mitigation activities, IDHS considers federal priorities for funding, priorities of the governor and legislature, and the cost-benefit of each proposed activity to ensure the greatest benefit for the funds expended. To this end, the state initially focused on the development of MHMPs in communities where population and growth were fueling rapid development. In response, many of these communities have developed strong, coordinated ordinances to discourage development in the floodplains. This has been relatively easy as these communities typically have large, open areas for residential and commercial growth.

The State has focused on these communities’ legacy areas where development had taken place prior to the delineation of floodplains and flood risk. It will continue to be necessary to maintain a priority to assist these communities in reducing existing risk by providing technical assistance, funding when available and working to integrating risk reduction into their comprehensive planning efforts.

These areas also have the most Repetitive Loss and Severe Repetitive Loss properties in the State, which positions them as the areas of highest vulnerability. Current prioritization is based primarily on repetitive loss status, financial status of the community (small and impoverished communities have priority), availability of funding, and federal mandates. Communities with the greatest number of Repetitive Loss and Severe Repetitive Loss properties are the first priority of the State’s planning and mitigation activities. Indiana has made significant strides in acquiring and demolishing more than 750 properties since 2008.

IDHS Mitigation is increasing its focus on non-flood related hazards through the development and funding of new projects for the state. These projects include actions to minimize the damages associated with severe weather and earthquakes. Going forward, the State Hazard Mitigation Officer will assess the need for projects minimizing the effects from other hazards identified in the plan.

10.4 Counties at Greatest Risk

While all Indiana counties are exposed to these risks, Table 57 identifies the top 5 counties within the state with the most flash flood, flood, tornadoes, high wind and thunderstorm wind events reported to NCDC from January 1, 2013 to October 31, 2018. It also includes the top 5 counties with the most repetitive loss and severe repetitive loss properties.

10.5 Policies Regulating Development

Indiana’s Home Rule statute grants local government units “all the powers that they need for the effective operation of government as to local affairs” (IC 36-1-3-2). These government units include
townships, cities, and counties. Planning and zoning fall within the local government unit’s purview. As a result, planning and zoning fall to local governments in Indiana, resulting in a lack of uniformity from one jurisdiction to the next. Indiana law does require that, if a municipality wants to exercise zoning powers, a plan commission adopt a comprehensive plan.

However, Indiana law IC 36-1-3-8 (7) states that a unit does not have the “power to regulate conduct that is regulated by a state agency, except as expressly granted by statute”. When a state law and a local ordinance govern the same activity, the ordinance yields to state law. Table 58 describes policies that regulate development in hazard-prone areas.

Table 58. Policies that Regulate Development in Hazard-Prone Areas

<table>
<thead>
<tr>
<th>Policy Area</th>
<th>Description/Applicability</th>
<th>Effectiveness</th>
</tr>
</thead>
<tbody>
<tr>
<td>Floodplain Management</td>
<td>IDNR, Division of Water coordinates with the NFIP; monitors compliance with state and local floodplain management standards; provides assistance in mitigation planning and techniques; identifies flood hazards. Pre- and -post disaster, local jurisdictions must comply with floodplain requirements regarding development in hazard-prone areas. The requirements include provisions for building and rebuilding (regardless of the nature of damage) in floodplains.</td>
<td>The Program outlines strict policies for new development in high-risk, hazard-prone areas. Structures must be elevated two (2) feet above the Base Flood Elevation of the floodplain. The local floodplain managers have reduced the number of damaged structures in hazard events through permitting and promotion of mitigation alternatives.</td>
</tr>
<tr>
<td>Coastal Erosion Management</td>
<td>The purpose of the Indiana Lake Michigan Coastal Program is to enhance the state’s role in planning for and managing natural and cultural resources in the coastal region and to support partnerships between federal, state and local agencies and organizations. The Indiana Lake Michigan Coastal Program relies upon existing laws and programs as the basis for achieving its purpose. There are 3 coastal counties in Indiana.</td>
<td>Coastal grant programs are available to local jurisdictions. The NFIP has not mapped flood areas along coastlines, but it has been estimated that 25 percent of homes and other structures within 500 feet of the U.S. coastline and the shorelines of the Great Lakes will fall victim to the effects of erosion within the next 60 years.</td>
</tr>
<tr>
<td>Zoning</td>
<td>Zoning is a locally enacted law that regulates and controls the development and land use of private property. It prevents development in inappropriate places (e.g., flood plains, steep ravines, lands with underground caves, etc…) and by regulating the use of land to protect flood prone areas.</td>
<td>The State continues to promote the importance of zoning as an effective method to minimize damage and encourages local jurisdictions to adopt zoning ordinances. Zoning is still a voluntary program, and continues to meet resistance in smaller, rural communities.</td>
</tr>
<tr>
<td>Land-Use Planning</td>
<td>The land use plan lays out land development goals and priorities. The plan details how specific parcels of property will be used, allowing safe and coordinated development. Land use plans take into consideration the hazards associated with any give area in a jurisdiction.</td>
<td>Some Indiana Residents consider land use planning an encroachment on their personal property, but the process allows jurisdictions to identify site-specific hazards and avoid development that places people or property in harm’s way. Still found mostly in larger cities and to some extent as economic development plans in smaller communities.</td>
</tr>
</tbody>
</table>
In 2017, Morgan County adopted a stricter building code in relation to development occurring in newly identified fluvial erosion hazard areas.

10.6 Status of Multi-Hazard Mitigation Plans

10.7 Mitigation Strategies and Actions

The goal of mitigation is to protect lives and build disaster-resistant communities through minimizing disruptions to local and regional economies, reducing the future impacts of hazards including property damage, and supporting best use practices for public and private funds spent on recovery assistance.

Each county and its participating communities share a common MHMP and worked closely to develop it. These communities work together with their city councils and their Emergency Management Agency
Director to insure that the hazards and mitigation actions included in their plan are accurate and addressed in their jurisdictions. The following table includes the top two to three mitigation strategies for each county with a current plan as of 12/31/2018.

**Table 60. Local MHMP Mitigation Strategies**

<table>
<thead>
<tr>
<th>County</th>
<th>Hazard</th>
<th>Mitigation Strategy</th>
</tr>
</thead>
<tbody>
<tr>
<td>Adams</td>
<td>Flood</td>
<td>Reduce flood insurance premiums through increased participation or advancement in the NFIP's CRS program</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Investigate possible incentives for (private) buildings with safe rooms</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Post information/warning signs in local parks and other public gathering places explaining what to do in case of a hazard event</td>
</tr>
<tr>
<td>Allen</td>
<td>Flood</td>
<td>Pursue additional buyouts in the City of Fort Wayne</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Obtain 800mhz radios for emergency response</td>
</tr>
<tr>
<td></td>
<td>Flood</td>
<td>Prepare a detailed Flood Response Plan (FRP) to improve response and reduce losses from a flood event</td>
</tr>
<tr>
<td>Bartholomew</td>
<td>Flood</td>
<td>Work with residential and critical facility property owners to buyout and mitigate properties subject to flooding</td>
</tr>
<tr>
<td></td>
<td>Severe Weather</td>
<td>Increase awareness and participation in mass notification, social media, weather radios, etc.</td>
</tr>
<tr>
<td>Boone</td>
<td>Flood</td>
<td>Conduct a detailed floodplain study for Mann Ditch</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Conduct a study to determine shelter capacity in the county</td>
</tr>
<tr>
<td></td>

<td>Flood</td>
<td>Countywide mass notification system</td>
</tr>
<tr>
<td>Montgomery</td>
<td>Severe Weather</td>
<td>Educate the public through public events, outreach programs, multilingual information, and encouragement of voluntary purchase of federally-subsidized flood insurance</td>
</tr>
<tr>
<td>Multiple</td>
<td>GIS layers for public safety officials with fixed facilities, public gathering places, additional GIS training, purchase Pictometry imagery, vehicular modems, and other mobile software</td>
<td></td>
</tr>
<tr>
<td>Morgan</td>
<td>Flood</td>
<td>Institute buyout program for flood-prone land areas along Lingle Road in Whitaker and Countyline and Edgewood</td>
</tr>
<tr>
<td>Flood</td>
<td>Purchase and set up permanent signage directing residents to shelters and warning of flash flooding areas</td>
<td></td>
</tr>
<tr>
<td>Flood</td>
<td>Establish setback ordinances for future development</td>
<td></td>
</tr>
<tr>
<td>Noble</td>
<td>Hazmat</td>
<td>LEPC continues to have exercises; review site and vicinity plans for all reporting facilitates; increase personnel certified for OSHA Level III</td>
</tr>
<tr>
<td>Multiple</td>
<td>Prohibit construction of critical facilities in known hazard areas, encourage back-up generators, ensure mobile homes are anchored, Investigate reciprocal agreements for damage assessment following hazard event, develop buyout/retrofit program, encourage new development to bury utility lines</td>
<td></td>
</tr>
<tr>
<td>Ohio</td>
<td>Multiple</td>
<td>Install back-up power generators for churches used as shelters</td>
</tr>
<tr>
<td>Multiple</td>
<td>Continued compliance of the NFIP for all NFIP communities by prohibiting future development in the special flood hazard area</td>
<td></td>
</tr>
<tr>
<td>Orange</td>
<td>Fire</td>
<td>Install back-up power generators for churches used as shelters</td>
</tr>
<tr>
<td>Multiple</td>
<td>Develop long-term strategies to educate residents on the hazards affecting their county</td>
<td></td>
</tr>
<tr>
<td>Owen</td>
<td>Multiple</td>
<td>Update and coordinate GIS layers with location and attributes of critical infrastructure; quantitatively estimate losses in scenarios; update Hazus-MH Earthquake model with local soil data for more accurate damage estimates</td>
</tr>
<tr>
<td>Hazmat</td>
<td>Maintain LEPC reporting and training efforts as required through SARA Title III and ensure current facility maps/response plans are on file for Tier II facilities</td>
<td></td>
</tr>
<tr>
<td>Parke</td>
<td>Hazmat</td>
<td>Create new or revise existing plans to hazards that affect Parke County; implement county drills for hazards</td>
</tr>
<tr>
<td>County</td>
<td>Hazard</td>
<td>Mitigation Strategy</td>
</tr>
<tr>
<td>----------</td>
<td>------------------</td>
<td>-------------------------------------------------------------------------------------</td>

11 State Capabilities

This section describes the State’s pre- and post-disaster hazard mitigation policies, programs, and capabilities to mitigate Indiana hazards. It also includes an evaluation of the state laws, regulations, policies, and programs related to hazard mitigation and development in hazard-prone areas. Specific capabilities are also described within the context of mitigation goals and objectives and proposed mitigation strategies in Section 9 of this plan.

The major challenge to all State programs is the limited funding available. Funding for all state programs has been steadily decreasing, making it more challenging to implement mitigation activities. Limited funding has also restricted the ability of state agencies to expand their staffing to enable program expansion.

11.1 Laws, Regulations, and Programs

IDHS utilized a revised version of FEMA form 386-3 (part of the mitigation planning series) to help determine specific mitigation capabilities of Indiana’s departments and agencies and identify the regulations and programs that support the mitigation process.

Indiana has a history of successfully implementing hazard mitigation through program development and project implementation. As previously stated, the agencies involved are active participants in the Silver Jackets and also the Indiana Association for Floodplain and Stormwater Management (INAFSM). INAFSM was founded in 1996 by professionals interested in and responsible for floodplain and stormwater management in the state of Indiana. Its members include federal, state, and local agency staff, engineers, consultants, planners, elected officials, members of academia, students, and floodplain residents.

Several state agencies promote programs that encompass pre- and post-disaster mitigation activities including the following.

11.1.1 Office of the Governor

Under Indiana Law, the governor is responsible for the coordination of all of Indiana’s emergency/disaster management system including mitigation programs.

The Office of the Governor’s activities include the following.

- **Disaster Assistance Appropriations**: The Governor can request appropriations from the General Assembly for disaster assistance whenever he/she deems it is necessary for the protection of all citizens. The Authority of an Executive Order can establish and require that the state, its agencies and departments, and local communities adopt mitigation.

- **Executive Order for the Adoption of Mitigation Strategies**: The Authority of an Executive Order can establish and require that the state, its agencies and departments and local communities adopt mitigation strategies, and principles as part of their governing or regulatory functions.
11.1.2 Indiana Department of Homeland Security Agency

IDHS serves as administrator and coordinator of the State’s mitigation projects that have been funded by the Federal government through FEMA under the Robert T. Stafford Act, Public Law 93-288. IDHS coordinates all situation and damage assessment operations in a disaster area. The agency routinely cooperates with federal, state and local governments to maintain and develop disaster preparedness, response, recovery and mitigation Plans. IDHS establishes and maintains an EOC to provide coordination and public information during emergencies and disasters.

IDHS’s activities include the following.

**Manages the State Hazard Mitigation Program:** The mitigation staff’s purpose is to promote mitigation statewide and to manage the FEMA mitigation Programs for Indiana.

**Hazard Mitigation Grant Program (HMGP):** IDHS administers this program, which is available after a Presidential Disaster Declaration. HMGP funds hazard mitigation plans and cost-effective projects that reduce or eliminate the effects of hazards and/or vulnerability to future disaster damage. Indiana has used HMGP funding for acquisition/demolition projects, elevation projects, installation of warning sirens, and mitigation planning.

**Pre-Disaster Mitigation (PDM) Grant Program:** IDHS administers funds from this annual, national competitive program. PDM funds hazard mitigation plans and cost-effective projects that reduce or eliminate the effects of hazards and/or vulnerability to future disaster damage. Indiana has used PDM funding for acquisition/demolition projects, residential and community safe rooms, and mitigation planning.

**Flood Mitigation Assistance (FMA) Program:** IDHS administers this program, which funds flood mitigation plans, provides technical assistance and funds construction projects that reduce flood risk to insured, repetitive loss properties. Indiana has used FMA funding for acquisition/demolition projects and mitigation planning.

**Encourages and promotes jurisdiction participation in NFIP:** IDHS requires good standing in the NFIP as a prerequisite to mitigation funding.

**Education and Outreach:** Mitigation Staff promotes pre- and post-disaster mitigation techniques, including retrofitting, NFIP, flood proofing, and construction of safe rooms, is imperative for prevention of damage from future events.

**Indiana State Disaster Relief Fund:** The fund is established to provide financial assistance to eligible entities for the costs of repairing, replacing, or restoring public facilities or individual residential real or personal property damaged or destroyed by a disaster and to assist eligible entities in paying for the response costs incurred by an eligible entity during a disaster. Eligible categories of work include:

- Debris Removal - deposited within the public right-of-way and equipment costs.
- Publicly Owned Transportation Systems - roads, streets, highways, bridges, and other public ways and their necessary appurtenances.
- Publicly Owned Buildings and Structures.
- Publicly Owned Water Control Facilities - dams, levees, dikes, ditches, and other drainage or flood control, or both, devices.
• Publicly Owned Recreation Facilities - parks, and recreation facilities.
• Publicly Owned Utilities: sanitary sewer systems, storm sewers, lift stations, or wastewater treatment facilities; and water treatment, water storage, or water distribution facilities.
• Other Infrastructure owned by or operated by or on behalf of an eligible applicant.

11.1.3 Indiana Department of Transportation

INDOT’s mission is to plan, build, maintain, and operate a superior transportation system enhancing safety, mobility, and economic growth.

Enhance Indiana’s Economic Competitiveness and Quality of Life

• Improve connectivity via multiple modes of transportation
• Increase understanding of Indiana’s position as it relates to the autonomous/connected vehicle industry, and undertake initiatives to advance testing and research in the state
• Support and encourage local agencies in their efforts to develop and implement sustainable plans for their futures

Execute a 20-Year Road and Bridge Plan

• Deliver the Next Level Roads plan to improve pavement and bridge quality, safety and mobility
  • Priority given to construction zone safety for workers and motorists
  • Focus on engineering, education, enforcement and emergency response
• Identify continuous improvements of the Asset Management process
  • Strive for improved collaborations with all stakeholders – internal and external
• Convey Next Level construction projects through effective and efficient communication strategies

Develop INDOT’s 21st Century Workforce

• Provide more complete job-training capabilities across the agency
• Provide employees with tools and information needed to succeed
• Deliver enhanced leadership training opportunities

INDOT’s activities include:

**Engineering and Design Practices:** Provides technical assistance for relocation of critical facilities, relocation of bridges and upgrading of culverts.

**Disaster Recovery and Repair:** Clears and repairs roadways interrupted by flooding, tornados and landslides. Promotes and utilizes mitigation measures throughout engineering and design process to prevent future damage.

**Education and Outreach:** The INDOT provides information to citizens on safety and prevention techniques and promotes severe weather awareness.
11.1.4 Indiana Department of Natural Resources

The mission of IDNR is to protect, enhance, preserve, and wisely use natural, cultural, and recreational resources for the benefit of Indiana's citizens through professional leadership, management, and education.

To satisfy such a broad and diverse responsibility, the Department is divided into two distinct areas of responsibility: the Regulatory Management Team and the Land Management Team. The Regulatory Management Team consists of the Divisions of Water; Entomology and Plant Pathology; Historic Preservation and Archaeology; Reclamation; and Oil and Gas. Outdoor recreation and land management programs are housed within the Land Management Team. That unit consists of State Parks; Nature Preserves; Land Acquisition; Fish and Wildlife; Outdoor Recreation and Forestry.

Its activities include:

- **Floodplain Management Program (in accordance with IC 14-28-1 Flood Control Act and IC 14-28-3 Floodplain Management Act):** IDNR, Division of Water coordinates with the NFIP; monitors compliance with state and local floodplain management standards; provides assistance in mitigation planning and identifies flood hazards.

- **Indiana Dam Safety Program (IC 14-27-7 Dams, Dikes and Levees Regulation Act):** Inspection, enforcement and permitting programs for dam and levees, classifies hazards and develops standards for dams and levees.

- **Conducts Hydrological Studies:** Maintains records of lake, stream and river levels necessary for proper identification of flooding hazards. Cooperates in USGS data-collection programs. Currently, more than 80 percent of the continuous hydrologic data-collection activity is maintained through efforts cooperatively funded by the IDNR and the USGS.

- **Protects Threatened or Endangered Species:** Coordination early in project development determines potential effects on threatened or endangered species. Also coordinates with US Fish and Wildlife.

- **Indiana Historic Preservation Office (in accordance with Section 106 of the National Historic Preservation Act):** FEMA, in coordination with the State Historic Preservation Officer (SHPO), ensures that the effects a proposed project may have on any district, site, building, structure or object that is included in or eligible for inclusion in the National Register of Historic Places are not adverse. If there are adverse effects, FEMA enters into consultation with the SHPO to avoid or mitigate effects to cultural resources and develop a project-specific agreement to identify the measures to mitigate the effects.

11.1.5 Indiana Geological & Water Survey

The mission of the Indiana Geological Survey is to provide geologic information and counsel that contribute to the wise stewardship of the energy, mineral, and water resources of the state. Since 1837, the health, safety, and welfare of Indiana's citizenry have benefited through a combination of Indiana Geological Survey activities.

Its activities include the following.
Consultation on geologic features and soil types, subsidence and slope stability: Carried out through a combination of the following activities: geologic sample and data collection and storage, information dissemination (in the form of published maps, reports and databases), educational outreach programs, focused research initiatives and cooperative investigations with governmental agencies, industries and educational organizations.

Focused research initiatives and cooperative investigations with governmental agencies, businesses and industries, and educational organizations

Geologic sample and data collection and archiving

Dissemination of information in many forms, including published maps, reports, databases, and educational outreach programs

11.1.6 Indiana Department of Environmental Management

IDEM’s mission is to implement federal and state regulations to protect human health and the environment while allowing the environmentally sound operations of industrial, agricultural, commercial and government activities vital to a prosperous economy.

Air Quality Programs

- The Air Monitoring Branch serves the public and IDEM by overseeing all aspects of air quality monitoring in Indiana including the maintenance of Indiana’s air monitoring network that measures regulated air pollutants covered by the Clean Air Act (CAA), the collection of air monitoring samples, and the handling and sharing of data collected from Indiana’s air monitoring network.
- Air Compliance and Enforcement
- Air Monitoring
- Air Operations
- Air Permits
- Air Programs

Land Quality Programs

The Indiana landscape is an essential part of our environment, economy, and community. We must use it properly and preserve it for future generations of Hoosiers. The Office of Land Quality (OLQ) is primarily responsible for protecting this valuable resource. To achieve its goal, OLQ enforces regulations to make sure businesses are managing waste in safe ways. This includes animal farms, which can create large amounts of manure. Additionally, OLQ regulates storage tanks to minimize the possibility and impact of any underground leaks. And if the environment or public health is put at risk due to contamination, OLQ ensures that cleanups are prompt and effective.

- Animal farms
- Environmental clean up
- Storage Tanks
- Auto Salvage
- Coal Combustion Residuals.
- Industrial Waste
Solid Waste
Waste Tire Program

Water Quality Programs
The mission of the Indiana Department of Environmental Management (IDEM) is to implement federal and state regulations to protect human health and the environment while allowing the environmentally sound operations of industrial, agricultural, commercial and governmental activities vital to a prosperous economy. The mission of IDEM’s Office of Water Quality (OWQ), under the oversight of the Assistant Commissioner of OWQ, is to concentrate on fulfilling IDEM’s mission where water quality is concerned. More specifically, OWQ is responsible for protecting public health and the environment by assessing the quality of surface water and groundwater through biological and chemical testing; regulating and monitoring drinking water supplies (including wellhead protection), wastewater treatment facilities and the construction of such facilities; and, protecting wetlands for proper drainage, flood protection and wildlife habitat. OWQ serves the citizens of Indiana through fulfilling responsibilities as set forth in the Clean Water Act.

- Blue-Green Algae
- Hoosier Riverwatch
- Storm Water Permitting
- Watersheds and Nonpoint Source Water Pollution
- Wetlands, Lakes and Streams Regulation

Its activities include the following.

Consultation: Identifies disaster and environmental concerns and issues surrounding mitigation projects.

Technical Assistance: Provides technical assistance concerning Superfund sites. Incorporates mitigation objectives whenever possible.

11.1.7 Indiana State Department of Health
The Indiana State Department of Health serves to promote, protect, and improve the health and safety of all Hoosiers through the following:

- Drug Overdose Prevention
- Emergency Preparedness
- Epidemiology Resource Center
- Health and Human Services
- Health Care Regulation
- Laboratory Services
- Tobacco Prevention and Cessation
- Women, Infants & Children (WIC)
- Center for Deaf and Hard of Hearing Education

Its activities include the following:
Identifies and monitors issues that may affect the public health within the area of a disaster, i.e. well contamination, disease and vector control: Promote integration of public health and health care policy; strengthen partnerships with local health departments, collaborate with hospitals, providers, governmental agencies, businesses, insurance, industry, and other health care entities; and support locally-based responsibility for the health of the community.

11.1.8 Indiana Economic Development Corporation

Indiana Economic Development Corporation (IEDC) programs and initiatives offer business support and expertise to companies that are investing and creating jobs in Indiana. The agency strives to improve quality of place, infrastructure, available development sites and regulatory assistance to build economic strength and opportunity that grows and attracts new business and talent.

From decreasing permitting time, to streamlining application processes, pre-certifying shovel-ready sites and increasing access to training and skills, IEDC is focused on creating new high-wage, high-skill opportunities for the next generation of Hoosiers. It places special emphasis on the automotive, life sciences, energy, and national security industry sectors, and supports companies involved in advanced manufacturing, logistics, information technology and research and development.

Indiana also provides financial assistance to qualified high-tech firms and small businesses and offers a variety of programs to support new business start-ups and business expansion and growth.

Its activities include the following.

- **Provides funding under the Community Development Block Grant Program and Economic Development Program for infrastructure construction/improvement and commercial property acquisition/relocation in designated mitigation projects**: Can supply matching funds to communities for acquisition/elevation projects under the Community Development Block Grant (CDBG) program. Provides technical assistance to communities through various programs.

11.1.9 Indiana Office of Community and Rural Affairs

OCRA works with local, state and national partners to provide resources and technical assistance to aid communities in shaping and achieving their vision for community and economic development.

Its activities include the following.

- **Funding for construction of housing through its low to moderate income housing, senior citizen housing, etc.**: Provides funding for relocation of floodplain residents through purchase of new housing.

- **Community Development Block Grants**: Provides federal funding to help rural communities with a variety of projects to include sewer and water systems, community centers, health and safety programs, and many others. These funds help communities improve their quality of life and ensure the health and safety of their citizens.

Over 40 loan, loan guarantee, and grant programs to finance housing, businesses, economic development, and community facilities and infrastructure. Eight key programs:

- **Business & Industry Loan Guarantees**: bolsters the availability of private credit by guaranteeing loans for rural businesses.
- **Water & Waste Disposal Loan & Grant Program:** provides funding for clean and reliable drinking water systems, sanitary sewage disposal, sanitary solid waste disposal, and storm water drainage to households and businesses in eligible rural areas.

- **Single Family Housing Guaranteed Loan Program:** assists approved lenders in providing low- and moderate-income households the opportunity to own adequate, modest, decent, safe and sanitary dwellings as their primary residence in eligible rural areas. Eligible applicants may build, rehabilitate, improve or relocate a dwelling in an eligible rural area. The program provides a 90% loan note guarantee to approved lenders in order to reduce the risk of extending 100% loans to eligible rural homebuyers.

- **Multi-Family Housing Direct Loans:** provides competitive financing for affordable multi-family rental housing for low-income, elderly, or disabled individuals and families in eligible rural areas.

- **Community Facilities Guaranteed Loan Program:** provides loan guarantees to eligible private lenders to help build essential community facilities in rural areas. An essential community facility is defined as a facility that provides an essential service to the local community for the orderly development of the community in a primarily rural area, and does not include private, commercial or business undertakings.

- **Community Facilities Direct Loan & Grant Program:** provides affordable funding to develop essential community facilities in rural areas. An essential community facility is defined as a facility that provides an essential service to the local community for the orderly development of the community in a primarily rural area, and does not include private, commercial or business undertakings.

- **Single Family Housing Direct Home Loans:** assists low- and very-low-income applicants obtain decent, safe and sanitary housing in eligible rural areas by providing payment assistance to increase an applicant’s repayment ability. Payment assistance is a type of subsidy that reduces the mortgage payment for a short time. The amount of assistance is determined by the adjusted family income.

- **Multi-Family Housing Loan Guarantees:** works with qualified private-sector lenders to provide financing to qualified borrowers to increase the supply of affordable rental housing for low- and moderate-income individuals and families in eligible rural areas and towns.

### 11.1.10 Indiana Finance Authority (IFA)

IFA’s mission is to oversee State-related debt issuance and provide efficient and effective financing solutions to facilitate state, local government and business investment in Indiana.

**Flood Control Revolving Fund:** Created to provide local entities loans with low interest to pursue a relevant flood control program.

Program includes:

- Removal of obstructions and accumulated debris
- Clearing and straightening channels
- Channel widening
- Building or repairing levees or flood protective works
• Construction of bank protection works

This fund is also available to a conservancy district to pay for the costs of establishing a district and costs associated with preparing the district plan for any of the purposes for which a district can be established.

• Loans may not exceed $300,000 to any one local entity
• Loan term = 10 years; 3% interest rate
• Fund monies do not revert to the state general fund.
• Fund monies are awarded on a prioritized basis

11.1.11 USDA Rural Development Community Programs

This is a federal community program established to finance drinking water treatment systems and wastewater treatment systems in rural communities. Community Programs also funds essential community facilities like hospitals, day cares, emergency response and assisted living. Programs focused on individuals include:

• Farm Labor Housing Direct Loans & Grants
• Individual Water & Wastewater Grants
• Multi-Family Housing Direct Loans
• Single Family Housing Direct Home Loans
• Single Family Housing Guaranteed Loan Program
• Single Family Housing Repair Loans & Grants
• Value Added Producer Grants
12 Plan Maintenance, Monitoring, and Evaluation

12.1 Plan Maintenance

The State Hazard Mitigation Officer (SHMO) will maintain the plan after each declared disaster for the continued relevancy of its goals and objectives. They will also determine whether funded projects have been effective in achieving these goals, and whether the strategies and measures have been effective in reducing losses caused by hazards.

In the past decade, Indiana has experienced several significant disasters that have allowed IDHS to adjust its focus on mitigation with the cooperation of local jurisdictions, other state agencies, and federal agencies. To prioritize mitigation funding for each disaster, FEMA and IDHS Mitigation incorporate issues identified by state and local partners since the last disaster.

In 2013, flooding in the central and northeastern parts of the state—where the State focused significant mitigation funding during the late 1990s and from 2002 to 2007—resulted in significantly less damages than would have occurred before the mitigation projects were implemented. Flooding of this magnitude would have resulted in hundreds of homes and businesses being damaged in the past. Most communities had some smaller pockets of damaged homes, but the event did not result in a disaster declaration. In recent disasters, a year, or even three, is not a significant amount of time to judge climatological events.

12.2 Plan Monitoring and Evaluation

It is the responsibility of the State Hazard Mitigation Officer to monitor and evaluate the state hazard mitigation plan. An important time for plan monitoring is post-event. The purpose of monitoring the plan at that time is to review and evaluate how effective the overall strategies worked to achieve the goals of the State and local hazard mitigation plans. The SHMO will coordinate with federal and local officials to evaluate if the designated strategies have been effective in reducing losses. IDHS Mitigation will facilitate discussions to determine if new or further mitigation strategies or activities are needed.

When there are no declared disasters, the SHMO will annually review and update, if needed, the SHMP to include other natural and man-made hazards that threaten the citizens of Indiana and modify, add, or delete mitigation goals and projects.

Since the 2014 update, there have been no major changes to the system of tracking mitigation activities and goals. The process is documented through the use of tracking tools to monitor progress and, when necessary, follow up by IDHS Mitigation. These tracking spreadsheets are maintained on a common drive for all of the mitigation section staff to access. A quarterly project site inspection will be performed to verify the information received in the submitted quarterly reports by grant sub-recipients. A closeout site inspection will be performed in conjunction with the project grant closeout. In addition, a site inspection will be performed once every three years to verify the property information submitted by sub-recipients to fulfill their post-closeout monitoring requirement.

The monitoring of projects and the closeout of grant processes are covered at length in the 2014 State of Indiana Administrative Plan for Hazard Mitigation Grant Programs. IDHS Mitigation will be updating this document in 2019, as a result of disaster declaration DR-4363-IN, received on May 4th, 2018.
Administrative Plan is meant to be a multi-grant program administration and grants management document. It is the means by which the IDHS’s Mitigation Section operates (Standard Operation Plan). Additionally, all mitigation grants awarded require that the local jurisdictions sign a state and local agreement that outlines the reporting requirements, both fiscal and narrative, of project progress and closeout requirements. It includes maintenance and post closeout requirements for the local jurisdiction. The following table lists the status of current grant funded mitigation projects within the state.

**Table 61. Status of Indiana Mitigation Activities (as of 1/31/2019)**

Christopher B. Burke Engineering, LLC. (2016). *White Lick Creek Assessment.*

10/10/2018

Attendees:
- Mary Moran – IDHS
- Torrey Glover – IDHS
- Kisha Morris – IDHS
- Alicia Schoening – IDHS
- Jim Sparks – Polis
- Kayla Kauffman – Polis
- Marianne Cardwell – Polis

Summary:
- The meeting started with introductions of all attendees.
- Schedule Discussion:
  - The team discussed the schedule for the plan and agreed to set internal deadlines and provide FEMA with the plan in sections to facilitate review. Marianne will provide a draft schedule, which Torrey will review prior to submission to Steve.
  - The team reviewed the 2014 plan and discussed areas that should be expanded. IDHS expressed a desire for more detail in section 7 or possibly moving the information in that section to section 6.
  - The team discussed the need for additional climate information in the plan. Polis staff shared that a National Weather Service representative who attended the LaGrange County Meeting 1 informed Polis staff of data availability in regards to future trends.
  - After some discussion about Census data and vulnerable populations, Polis staff suggested having one of its own, Unai Miguel, do a brief presentation during the next meeting about the Census data available along with various models for identifying vulnerable populations. IDHS expressed interested.
  - IDHS provided a climate contact: Melissa at Purdue. Torrey will make introductions via email.
  - Torrey requested that he be copied on all emails related to the plan.
  - A good contact for earthquakes is Michael Hamburger at IU Bloomington. The team agreed that his input should happen sooner rather than later to ensure that the models developed for the plan are up-to-date.
  - IDHS mentioned that the Indiana State Hazard Planner, Allison Curry, will also be involved with earthquakes.
  - IDHS suggested the input of Dave Smith, IDNR, for drought information.
  - The Polis team will work on pros and cons of

Action Items:
- Polis:
  - Marianne to send Torrey a list of the information needed for section 1.
  - Marianne to verify Bing building numbers for Indiana.
  - Polis to break down data needs for sections 1 through 5 and provide the info to Torrey.
- IDHS:
  - IDHS to obtain individual and public assistance information for section 1.
10/17/2018

Attendees:
- Torrey Glover – IDHS
- Kisha Morris – IDHS
- Alicia Schoening – IDHS
- Kayla Swoveland – Polis
- Jim Sparks – Polis
- Unai Miguel Andres – Polis

Summary:
- The meeting began with introducing Unai to the IDHS team.
- Unai began his presentation for the team on the uses of SAVI & 211 data.
- After the SAVI & 211 presentation Jim & Kayla informed the IDHS team that the Polis team was still unsure of how to replicate the CAPI ranking for the state plan. The discussion went to potentially using information from SAVI & 211 to replicate the vulnerability ranking in a new way.
- Kayla & Jim agreed to reach out to John Buechler to ask about how CAPI was created during the last plan.
- The team decided that by the next meeting (10/24) we would determine when to host the meeting for the IDNR group.
- The team also talked about when to bring in the climate team and decided that, if possible, they would aim to engage that team on the 10/24 meeting date.
- Torey also reminded Jim that the quarterly county MHMP status report was needed.
Action Items:
- Polis:
  - Reach out to John Buechler about CAPI assessment in the 2014 plan
  - Submit quarterly report

Summary:
- Section 1 Plan Review:
  - Discussed 2014 plan disaster numbers, which seem to be exactly double of what they should be. Torrey agreed to review the numbers to make sure that the 2019 plan numbers are correct.
  - Marianne proposed a new chart format for figure 2. The team indicated a preference for the new format.
  - The team discussed how federal disaster declarations seem to be more difficult to obtain and that the federal government is emphasizing pre-disaster mitigation. Polis will include a paragraph about this in section 1 and change the HMGP chart to show this trend. Torrey will provide HMGP and PDM funds information to Polis.
The team agreed to set the range from 2008 to 2017.
Marianne indicated seeing references to appendices in the 2014 plan but not finding the appendices anywhere. IDHS suggested asking FEMA if they have it. Polis will contact Steve Greene.

- CAPI, established by FEMA region 5 and used in the 2014 state plan, is no longer in use. The team briefly discussed alternatives. Marianne will look at the Wisconsin plan to see what may have been used there.

- Focus Groups:
  - The team discussed the scheduling of various focus groups. Marianne will reach out to the climate team members to check on availability for the next meeting (10/31/18). Torrey will contact IDNR & INDOT for availability on either 11/7 or 11/14 meeting. Marianne will reach out to the earthquake team to see about a late November meeting (11/28).
  - Marianne mentioned putting together a more detailed scope of work for the counties. Torrey requested a copy of it for reference.

**Action Items:**

- **Polis:**
  - Marianne to send out updated disaster declaration dollars that exclude 2018 disasters.
  - Marianne to add a paragraph to section 1 that discusses the rise in pre-disaster mitigation federal funds and the decrease in federal disaster declarations. Possibly mention the new Disaster Recovery Response Act.
  - Marianne to add a chart to section 1 that compares HMGP/PDM funds to obligated IA/PA funds.
  - Polis to change the decade range to 2008 through 2017 (excluding 2018).
  - Marianne to ask Steve Greene (FEMA) whether he has a copy of the 2014 state plan that includes appendices.
  - Marianne to make sure that DR-1766 is mentioned in section 1.
  - Marianne to report back on findings about new risk assessment index that FEMA may be developing.
  - Polis to check Wisconsin plan to see which vulnerability index they may have used.
  - Marianne to reach out to Purdue to see if the climate team is available to meet next Wednesday (10/31)
  - Marianne to reach out to IU earthquake team to see if they are available on Wednesday 11/28.
  - Marianne to send out new proposed scope of work to Torrey.

- **IDHS:**
  - Torrey will double-check the disaster declaration dollars to make sure that there are no errors.
  - Torrey to reach out to DNR and INDOT to see if they are available to attend on either 11/7 or 11/14.
  - Torrey to send out PDM & HMGP funding information.
  - Torrey to inquire about status of State Disaster Relief Fund funding information.
10/31/2018

Time: 9AM – 11AM

Attendees:
- In person:
  - Mary Moran – IDHS
  - Torrey Glover – IDHS
  - Kisha Morris – IDHS
  - Alicia Schoening – IDHS
  - Jim Sparks – Polis
  - Kayla Swoveland – Polis
  - Marianne Cardwell – Polis
- Via phone (1.669.900.6833, meeting ID 531-141-9779):
  - Crystal Pettet – NOAA
  - Sam Lashley – NOAA
  - Tom Reaugh – NOAA
  - David Smith – IDNR
  - Molly Woloszyn – NOAA
  - Beth Hall – University of Illinois
  - Dev Niyogi – Purdue University
  - Melissa Widhalm – Purdue University
  - Mike Timlin – University of Illinois

Summary:
- Climate Discussion:
o The meeting started with introductions of everyone attending the meeting, both in person and via phone.

o Marianne and Torrey explained the goal of the meeting.

o Dave recommends including record days, days above and below a certain temperature, heating and cooling days, trends, annual and extreme precipitation information, as well as numbers of days of sunshine.

o Mike said he had a lot of the information Dave listed, broken down by month. Mike will email Marianne the URL to the Midwest Climate Center site that lists this information.

o Beth mentioned that the University of Illinois (Illinois) has been looking at whether numbers have been updated in terms of the 100-year and 500-year flood thresholds as those were established decades ago. She asked whether Indiana had also done that. Dave said it’s been done in certain locations but not for a larger region.

o Mary saw a presentation about shorter and more intense rain events that included information that would be good to include in the plan. Sam said that this was his presentation and he can provide the information to the team. He has the information on an annual basis but the next step includes breaking it down by month and even by county.

o Dev has a PhD student looking at trends of extreme precipitation. Her thesis is available online. Dev will provide the team the URL to the thesis.

o Melissa oversees reporting efforts at Purdue for the Indiana climate change assessment. The March ’18 report (Indiana Past & Future Climate Report) has a lot of information that could be useful for the climate section of the plan. It also has an associated report with historic climate. She will send the links to the team. Melissa offered to help with the customization of the graphics for the plan. The report is a collaborative effort with Indiana University, Purdue, Notre Dame, and the Midwest regional Climate Center (MRCC). Further information is available at IndianaClimate.org. Beth & Sam recommend starting with this report.

o Sam indicated that the number of flooding events are increasing. He also has information on the number of events per county, starting in the late 1980s/early 90s. The number of events in Southern Indiana have increased. There is also a new report about tornado frequency. Tornado alley is moving east, which puts certain portions of Indiana at an increased risk. In terms of lake effect events, the science is still unclear how climate change will impact it. Sam added that there is more temperature variability in the winter months, which affects roads as was seen in early 2018. Sam will send this information to the team.

o Mary noted that Torrey is currently working on a safe room program for tornadoes and is very interested in the tornado information that Sam has.

o Dev asked how the plan will be used. Mary answered that the plan is the result of a federal requirements for building resilience. It is also needed for federal disaster assistance. All projects that the state thinks are priorities must be referenced in the plan to get funding.

o Dev worked with North Carolina after hurricane Floyd and with New York City on resiliency plans. One approach is to look at trends and parameters and changes in events. For example, if the ground is dry, it can absorb larger amounts of rainfall whereas if the ground is wet, just a little bit of rain can cause flooding. We should be looking at the combination of events that can cause issues. Mary indicated that the state if updating its Threat and Hazard Identification and Risk Assessment (THIRA), which looks at those types of circumstances.
Dev said that much of what we know are from global models, which do not account for urban issues. Mary wants to include a section of the effect on cities. Dev indicated he can help with this.

Mary is attending a meeting tomorrow (11/1/18) on THIRA and will share what she learns with the team.

Dev has some drought information but it is not ready to publish. He is looking at water evaporation with Dave Smith. He has precipitation and evaporation maps he can provide.

Molly mentioned that she focuses on drought, which she recommends be included in the plan, especially “flash droughts” and their agricultural impacts. Flash droughts can also have impacts at the municipal level as they have impact on water. Beth offered to help Molly with putting together this information.

Tom suggested that the plan should include information about the different climate change forecasts that exist. It should also show how different areas of the state are impacted. He seconds the inclusion of drought information and can work with Molly and Beth. Tom will send information on different global projections.

Alicia asked about pollution. Mary indicated that due to the compressed timeframe, we may not have the opportunity to discuss this in the plan.

Torrey shared that we are on an accelerated timeframe, which means that the team will not be able to do everything that it had hoped to do. He would like to touch on water quality but there may not be time for it.

Marianne suggested including ozone days, which was mentioned in passing earlier.

Dave indicated that Melissa may have information on pollution. Melissa said she is releasing information on a rolling basis. She has had challenges with quantifying metrics related to health. She hopes to conduct more research in the future but recommends looking at the health report.

Melissa recalled working on a report a couple of years ago with Lacey from the Polis Center but could not find the document. Jim indicated that Lacey no longer works for Polis; however, Mary has a copy of the report and will share it with the team.

Dev recommends focusing on hydrographic and temperature extremes.

Marianne asked about snow and thunderstorms and whether there are any expected changes for those. Mary suggested that we separate those different weather-related events in the plan vs. grouping them.

- **Core Team Discussion:**
  - Torrey has received the needed information for section 1 and will send it to Marianne.
  - The IDHS team indicated their approval of the proposed cover page. It was suggested that the attribution of the picture be moved to the acknowledgement section and that the picture include a location but to remove the description.
  - Torrey confirmed that the declaration dollars in the section 1 draft are correct.
  - Marianne confirmed that FEMA did not have the appendices mentioned in the 2014 plan.
  - The team discussion Section 5 of the plan. We will replace the “projects” section with the section 5.4 goals and their status. Torrey will write the new goals. Mary recommended including Governor Holcomb’s 5 pillars into the goals. The team decided to move portions of the 2014 plan’s section 5.2 to the flooding section. The plan should show a comparison of the 2014 and 2019 riskMAP status. It should also include statistics on the NFIP coverage percentage. IDHS has access to the database that includes that information. Mary will provide the information to Torrey.
After review of the mitigation strategies in the 2014 plan, the team decided to combine the strategies into a single section within the plan, after the hazard identification section.

Polis will combine all of the 2014 mitigation strategies into a single Excel spreadsheet and provide to Torrey.

The team discussed repetitive loss data. Marianne will discuss with Jim what he had to do to obtain this information.

IDHS will review the list of hazards on page 35 of the 2014 plan to ensure that this list is still correct.

Alicia will dig up the information on the state-owned facilities.

**Action Items:**

- **Polis:**
  - Provide IDHS with a single Excel spreadsheet with the 2014 mitigation strategies.
  - Marianne to talk to Jim about what he had to do to get the repetitive loss information.

- **IDHS:**
  - Torrey to send the remaining section 1 information to Marianne.
  - Send Polis a copy of the 2011 plan.
  - Mary to provide Torrey with the NFIP data.
  - IDHS will review the list of hazards on page 35 of the 2014 plan to ensure that this list is still correct.
  - Alicia will dig up the information on the state-owned facilities.

- **Climate Group:**
  - Mike will email Marianne the URL to the Midwest Climate Center.
  - Sam will provide the team the presentation that Mary saw.
  - Dev will provide the team the URL to the extreme precipitation thesis.
  - Melissa will send the Indiana Past & Future Climate Report information to the team.
  - Sam will send tornado and flooding events information to the team.
  - Dev to help with the section on the effect of climate change on cities.
  - Dev to provide precipitation and evaporation maps.
  - Molly, Beth, and Tom to provide drought information.
  - Tom to provide information on different global projections.
11/07/2018

Time: 9AM – 11AM

Attendees:
- Mary Moran – IDHS
- Torrey Glover – IDHS
- Kisha Morris – IDHS
- Alicia Schoening – IDHS
- Kayla Swoveland – Polis
- Marianne Cardwell – Polis

Summary:
- **County Plans:**
  - Alicia asked about the status of the Henry County invoices. Marianne will send this out.
  - Alicia asked for the Henry County in-kind match documentation. Kayla will send this out.
  - Polis asked about the contact information for Cass County. Alicia will reach out.
- **State Plan:**
o The team discussed the documentation provided by the climate team and reviewed the proposed structure for section 2. Section 2.1 will discuss geography and topography of the state; Section 2.2 will discuss climate, including subsections on past & current climate and future climate; Section 2.3 will summarize natural hazards affecting the state. The rest of the sections will be similar to the 2014 plan.

o Polis will include the effects of climate change on Indiana, including the impacts on agriculture, combined sewer overflows, roads, and pests.

o Marianne asked about the status of the Section 1 data needs relating to the State Disaster Relief Fund. Torrey reached out to Manuela and if he does not hear back from her on Thursday, will inform Mary. Depending on when Polis receives the remaining information, the first section may not get finalized until next week.

o The team discussed the Section 4 priority rankings. Mary explained that the state was to deliver the state THIRA to FEMA by December 1, 2018. Additionally, all district THIRAs should be done by that date. Mary recommends setting up a meeting with Torrey and the THIRA team to obtain the information needed for pages 36 to 39 (2014 plan) of section 4.

o Critical facilities for section 4: Alicia has received information on accessing the list of critical assets using Falcon Viewer. However, she may need additional assistance to extract the necessary information. Kisha may be able to help. Kayla indicated that Polis already has a list that was put together with Burke earlier in 2018 but Polis would still like to have the state list to compare it to its list. Torrey requested that the hospitals be broken out from the care category. Mary indicated that EMS (Robin Stump) may have this information.

o State-owned facilities for section 4: Alicia will reach out to Brian Renner at IDOA for the state-owned facilities. This data may be sensitive. Marianne indicated that at this time, Polis only needs a number to include in section 4. More detailed information may be needed in future sections.

- Previous Action Items:
  o Repetitive loss information: Marianne explained Steve Greene (FEMA) provided us with instructions on how to obtain the information. Jim Sparks sent the letter to Mary Beth Caruso, FEMA Region V Mitigation Division Director, on Monday. Jim has not yet heard back. Marianne will provide the letter to Torrey.
  o The team clarified that Mary needs to give Torrey the statistics on which counties have NFIP and which do not.
  o The team reviewed the hazards listed on page 35 of the 2014 plan. All hazard should be kept. Torrey requested that for the levee/dam failures section, a paragraph be added to indicate that failure could be due to natural events. Marianne asked if low-head dams should be included and the team agreed. Torrey will provide Polis information on low-head dam deaths and mitigation projects.
  o Marianne asked the team whether IDHS would like to review the draft climate section prior to sharing with the climate team. Torrey requested doing so. Once the scope of the section is finalized and approved by IDHS, it will be shared with the climate team.
  - Torrey will invite IDNR and INDOT today for the 11/14 meeting. Polis will send out an agenda/outline for that meeting to Torrey prior to the meeting.
  - Polis staff inquired about the status of the contract. Mary and Torrey indicated that they are pushing to get it finalized as soon as possible.
- **Polis:**
  o Marianne to provide Alicia with the status of the Henry County invoices.
  o Kayla to provide Alicia with Henry County’s in-kind match information.
  o Polis to include discussion of effects of climate change on Indiana.
  o Polis to add a paragraph indicating that levee/dam failures could be due to natural events.
  o Polis to add a section on low-head dams.
  o Polis to provide a draft climate section next week to Torrey.
  o Polis to provide Torrey with an agenda/outline for the INDOT/IDNR meeting prior to the meeting.

- **IDHS:**
  o Alicia to determine the right contact information for Cass County and will inquire at to the county’s status.
  o Mary to set up a meeting with Torrey and the THIRA team.
  o Alicia to obtain the list of critical facilities and provide it to Polis.
  o IDHS to reach out to Robin Stump (EMS) for hospital information.
  o Alicia to obtain the number of state-owned facilities from Brian Renner at IDOA and provide that information to Polis.
  o Torrey to provide Polis information on low-head dam deaths and mitigation projects.
  o Torrey to review draft climate section prior to sending to the climate team for review.
  o Torrey to invite IDNR and INDOT today for the 11/14 meeting on 11/7.
# APPENDIX A

## MEETING MINUTES

### 11/14/2018 (AM)

**Time:** 9AM – 11AM  
**Attendees:**

- Mary Moran – IDHS
- Torrey Glover – IDHS
- Kisha Morris – IDHS
- Alicia Schoening – IDHS
- Jamie Miller – IDNR
- Anita Nance – IDNR
- Kayla Swoveland – Polis
- Marianne Cardwell – Polis
- Matt Riggs – Polis
- Jim Sparks – Polis

Summary:

- County Plans:
  - Benton County: Marianne asked Alicia if the agreements between the county and the state were in order as the EMA Director, John Fields, had not seen the paperwork. Alicia indicated that it was and that the period of performance ends on 10/18/19

- State Plan:
  - The team agreed on the new look of the plan.
    - Section 1:
      - Marianne highlighted a few portions of section 1 that need IDHS’ attention.
      - The team agreed to take out the reference to Appendix B in the first paragraph.
      - The team agreed to replace the most recent disaster to the 2018 disaster but mention in the text that the plan focuses on 2008 through 2017 disasters and does not include 2018.
      - Mary asked to restructure the types of assistance portion of the text as well as add information about the HUD Disaster Recovery Fund and the FEMA Hazard Mitigation Grant 406.
      - Mary will edit the paragraph following the types of assistance.
      - The last paragraph on page 2 needs updated numbers from INDOT.
      - Marianne will make the edits and send to the team for review.
      - Once reviewed and acceptable to all, Marianne will submit to FEMA, copying Torrey.
    - Section 2:
      - IDHS was happy with the new climate section draft that was provided earlier in the week.
      - Marianne will submit to the climate team for their feedback.
  - Plan restructure:
    - Marianne reviewed the proposed restructure of the plan, which would look as follows:
      1. Introduction
      2. State Profile
      3. Planning Process
      4. 2014 Strategies Progress
      5. Risk Assessment Overview
      6. Natural Hazards
      7. Technological Hazards
      8. Human Hazards
      9. Mitigation Strategies
10. Local Capabilities
11. State Capabilities
12. Plan maintenance, Monitoring, and Evaluation
   ▪ The team agreed with the new structure.
   ▪ Marianne will send out an updated schedule reflecting the new structure.

- IDNR Conversation:
  o The IDNR conversation started with the introduction of the participants and a brief overview of the plan and its benefits.
  o The team discussed points of contacts within IDNR:
    ▪ Insurance programs: Anita
    ▪ RiskMAP: Dave Kipe
    ▪ State NFIP Coordinator: Darren Pearson
    ▪ Dam Safety: Jamie or George Crosby
  o The team discussed potential datasets that could be helpful for the plan:
    ▪ Dam inventory (Jamie): includes IEAP attribute indicating preparedness. 170 of the high hazard dams have IEAPs. These are only dams under the state’s jurisdiction and does not include federally-regulated dams.
    ▪ Low head dams (Jamie): there is an inventory of low-head dams but the dataset is not in good shape. The state is working on a living inventory of low-head dams. The plan should include information on how and who the state is building this inventory. The plan should also mention progress made to remove low head dams.
    ▪ Bridges: INDOT may have an inventory. Bridges can cause issues with debris during flood events.
    ▪ Landslide dataset: INDOT.
    ▪ Flood boundary datasets (Dave Kipe): there are two major datasets:
      ▪ Digital Regulatory Flood Boundaries, which are missing about 4 to 5 counties.
      ▪ Best Available Data: includes digitized paper maps for the 4 to 5 missing counties. It also includes 10,000 miles of unmapped floodways. The plan should include a description of this.
    ▪ Model library of flood boundaries: a statement should be included in the plan about this data.
    ▪ Benchmarks
    ▪ Division of water has an online research center application (Anita).
    ▪ Wetlands (Chris Ritz at NRCS, possibly also Ashley Moore). A map of wetlands should be added to section 2.
    ▪ Freshwater lakes (Jamie): a map of these should be included in section 2.
    ▪ Flood erosion hazards (Matt Riggs first, then Bob Barr, Siavash): the FEH report should be included as an appendix.
    ▪ The plan should include one or two paragraphs on the state’s stream gage network and flood inundation mapper sites (Silver Jackets). A mitigation strategy should be added to expand the state’s gage network in order to build the state’s resilience.
    ▪ Drought (Mark Basch and Dave Smith).
    ▪ National levee inventory (Jamie or George Crosby).
    ▪ Non-levee embankments: mention the examples of Morgan County (Matt) and Knox County (Anita).
    ▪ Wildfires (Carrie Tauscher, state urban forester)
2014 Mitigation Strategies:
- Marianne will share the spreadsheet with the team.
- The team will need to update the status of the 2014 strategies and will need input on new strategies.
- Mary asked Torrey to forward the spreadsheet to Ashley Moore for dissemination.
- Marianne suggested hosting the spreadsheet online so there is one central location for all input.

Action Items:
- **Polis:**
  - Marianne to update Section 1 and submit to IDHS for review.
  - Marianne to submit Section 1 to FEMA upon review/approval from IDHS.
  - Marianne to submit Section 2 – Climate to the climate team for review.
  - Marianne to submit updated schedule to Torrey.
  - Matt to provide the FEH report.
  - Include 1 or 2 paragraphs on the state’s stream gage network and flood inundation mapper sites relying on Silver Jackets as needed.
  - Add a mitigation strategy to expand the state’s gage network in order to build the state’s resilience.
  - Matt to provide language on NLE example in Morgan County.
  - Provide online 2014 mitigation strategies spreadsheet
- **IDHS:**
  - Review Section 1.
  - Mary to edit a paragraph in Section 1.
  - Torrey to forward the 2014 mitigation strategies spreadsheet to Ashley Moore for dissemination.
- **IDNR:**
  - Jamie Miller – provide the following datasets:
    - Dam inventory.
    - Existing low-head dams dataset.
    - Freshwater lakes
    - National levee inventory
  - Anita Nance – provide the following:
    - Division of Water online research application URL.
    - Language on NLE example in Knox County
  - Dave Knipe – provide the following:
    - Digital regulatory flood boundaries.
    - Best available data (flood boundary datasets).
  - Chris Ritz – provide the following dataset:
    - Wetlands.
  - Mark Basch or Dave Smith – provide information on:
    - Drought.
  - Carrie Tauscher – provide information on:
    - Wildfires
  - Unclear:
    - Model library of flood boundaries URL.
    - Benchmarks dataset.

Summary:

- This meeting focused on earthquakes and related natural hazards in Indiana. The conversation started with the introduction of the participants and a brief overview of the plan and its benefits.
- Marianne listed the three earthquake scenarios included in the 2014 state plan:
  - 6.8M in Mt. Carmel, KY
  - 7.7M in Barlow, KY
  - 500-year probabilistic scenario
- Kayla added that a 4th scenario is used in Polis’ county plans, which is an annualized analysis.
- Allison is currently working on a Wabash Valley-specific earthquake plan with a magnitude greater than 7 where the whole fault is shifting.
- Michael suggests running some additional scenarios:
  - Moderate earthquake (5.8) anywhere in the state. This could be centered near the Fortville Fault near Indianapolis.
  - A Wabash Valley earthquake, possible a 6.2M near Darmstadt near Evansville.
  - Historic recording of 5 to 6 earthquakes in the 1930s in western Ohio.
  - Paleoseismic record.
- Mary supports Michael’s recommendations.
- Michael encourages the team to run the probabilistic scenario as it is a good baseline for determining how hazardous each area is.
- Jim recommended we document in the plan which each scenario was chosen. The team agreed.
- Jim recommended a paragraph be included to point out that these earthquakes could happen anywhere.
- The 2014 plan focused on southwestern Indiana but the team recommends including additional areas.
- Jim noted that magnitude was not the only important parameter but that depth matters as well. Michael recommended that language be added that describes what matters, such as depth, fault type, orientation, etc.
- Mary wondered about soil types. Michael said that the shake maps he can create take soil types into consideration. Marianne noted that a soils map and a liquefaction map are included in the HAZUS analysis. Anna & Michael will provide the best soils & liquefaction datasets for Polis to use in its analyses.
- Mary noted that someone at INDOT is working on a GIS layer of roads that would be affected by landslides. Mary will look for the contact and data. She also mentioned that during the 2008 floods, there were many landslides. Michael indicated that he would be interested in a historical record of these and Mary said she would look for that information.
- Michael recommends that the plan mention paleoliquefaction, etc. The plan should include a map with paleoearthquakes besides just the recent ones. The map should also show data from surrounding states and not just Indiana.
- Michael mentioned that earthquakes can also be induced, mainly from gas/oil industry activities. Southwestern Indiana is most affected.
- Anna has a tool that provides regional estimates of landslides and liquefaction. This could turn into a sort of alert level.
- The team discussed the use of shake maps as inputs to HAZUS. Polis staff will discuss with Kevin Mickey and the team will try a shake map to test this out.
- Michael asked about whether the plan would analyze the impact of earthquakes on bridges, critical infrastructure, utility networks, etc. Due to time limitations, the plan may not include this, but the team will see if INDOT could support this effort. Some form of “shake cast” map for southwestern Indiana may be helpful. The plan should mention this information in a paragraph, including compounding effects of disasters, possibly leading to environmental consequences, such as pollution.
- Mary would like the plan to include information about confined feeding operations, coal ash sites, etc.
- Allie asked whether anyone has a dataset with unreinforced masonry buildings in the state. Mary will reach out to a contact at Purdue to see if such a dataset exists. Michael suggested using information such as building age and number of stories. Jim indicated that that Indiana Local Government Finance dataset includes this information and could be a potential source of information.
- Michael asked whether building codes reflected any of this information. Mary indicated she is working with the building commissioner’s office. The goals for 2019 are to increase and enforce building codes. Marianne asked whether the state could require more stringent building codes and Mary indicated that there are state building codes but most are regulated at the county level. Michael requested information about this and Mary said she would provide it.
- Anna asked whether the plan would look at sinkholes. The plan is slated to include information about this and the county plans already do. Anna will provide her data layer of sinkholes.
- There is a need for public input during the process. Torrey will clarify with Steve when and how public input is needed.

Action Items:

- Polis:
  - Work with Kevin Mickey & Michael to ensure shake maps will work.
  - Include information about confined feeding operations and coal ash sites.
  - Look into using IDLG to identify structures in Indiana that would be more susceptible to earthquake damage.

- IDHS:
  - Mary to reach out to INDOT to find the GIS layer of roads affected by landslides.
  - Mary to find the 2008 flood-related landslide information and share with Michael.
  - Mary to reach out to Purdue to inquire about existence of unreinforced masonry buildings in Indiana.
  - Mary to provide information about building codes to Michael.
  - Torrey to reach out to Steve at FEMA to clarify the public input process.

- Michael Hamburger:
  - Provide suggested scenarios, including:
    - Location (latitude/longitude)
    - Magnitude
    - Depth
- Description of why chosen
  - Provide a shake map for one of the scenarios for testing.
  - Language explaining what impacts the severity of an earthquake (magnitude, depth, fault type & orientation, etc.)
  - Dataset with paleoearthquake locations along with a paragraph.
  - Paragraph describing induced earthquakes.

  - Anna Jessee:
    - Regional estimates of landslides and liquefaction.
    - Sinkhole dataset.

  - Anna & Michael:
    - Provide Polis with the best soils and liquefaction GIS datasets.
    - Provide Polis with a “shake cast” map for SW IN.

11/28/2018

Time: 9-11AM

Attendees:
- Mary Moran – IDHS
- Torrey Glover – IDHS
- Kisha Morris – IDHS
- Alicia Schoening – IDHS
- Allison Curry – IDHS
- Kayla Svoveland – Polis
- Marianne Cardwell – Polis

Summary:
- Section 1:
  - The team reviewed IDHS’s comments on section 1. Marianne will update this section of the plan and provide to Torrey for a final review prior to submitting to Steve Greene.

- Section 2:
  - Marianne received comments from both Tom Reaugh and Melissa Widhalm on the new climate section. Melissa is currently reviewing an updated version.
  - Mary asked for a legend on the terrain map. If not possible, she suggested removing the map.
  - Torrey will provide Marianne with a scan of the annotated climate section. Marianne will update accordingly.

- Section 4:
  - The IDHS team will review the 2014 strategies and update them as a team to avoid overwriting each other’s comments.
  - The IDHS team will write the section’s introductory paragraph.
  - Marianne suggested including some kind of chart after the introductory paragraph to show overall progress. Mary suggested a map of projects or mitigation dollars spent in the state. Mary & Torrey will look at possible data from Falcon.
  - All language and strategies are due to Polis by Friday December 14 in order to finalize the section for submittal to Steve Greene by December 21.

- Section 5:
  - The team reviewed a draft of section 5.
  - The team agreed to keep the Most * Disaster entries. Mary will provide some language for 4363.
  - Marianne to update Table 1 as there were errors, along with separating out state from federal entries. Mary to look into the data that Manuela provided as there were some line items that may be incorrect.
  - The team discussed whether the state is doing a THIRA or a HIRA. Mary to confirm.
  - Mary noted that the new THIRA may be using different guidelines for hazard prioritization. She will confirm.
  - Alicia confirmed there are 174 hospitals in the state. Marianne will update Table 4 in Section 5 to indicate 174 hospitals but only 3,321 care facilities.
  - Marianne explained the use of Bing buildings for the analysis. She will work on Table 5 using the Bing buildings and also using just the IDLGF data and provide the numbers to the IDHS team.
- Section 6:  
  o Marianne and Kayla discussed Polis’ approach to the analysis for section 6, especially as it relates to flood, but also earthquakes.  
  o The team agreed to show the flood information by IDHS District and counties instead of watersheds. Polis will also provide additional information, such as content loss, inventory loss, damage ratio, shelter, debris, displaced households, and direct economic loss.  
  o Mary requested the addition of a paragraph explaining that our analysis is using Indiana-specific data, not out-of-the-box HAZUS data.  
  o Marianne mentioned the possibility of using state LiDAR data for the flood analysis, but indicated that there may not be enough time to do so. Mary & Torrey agreed to skip the use of the LiDAR data until the next version of the plan when more detailed LiDAR will be available for the whole state.

- Section 9:  
  o IDHS indicated that the Indiana University Environmental Resilience Institute may have new strategies to include in the plan. The team may want to meet with Institute staff to go over those strategies.  
  o The 2019 strategies will need to have a column that indicates the hazard(s) they address. The list should be sorted by priority.

**Action Items:**

- **Polis:**  
  o Marianne to submit updated section 1 to Torrey.  
  o Marianne to submit IDHS-approved section 1 to Steve Greene.  
  o Marianne to update table 1 in Section 5.  
  o Marianne to update Table 4 in Section 5.  
  o Marianne to provide Table 5 in Section 5 to the team based on 2 scenarios: Bing buildings with IDLGF data and just IDLGF data.  
  o Marianne to add a paragraph to Section 6 explaining the use of Indiana-specific data with HAZUS.

- **IDHS:**  
  o Torrey to review finalized Section 1.  
  o Torrey to provide annotated climate section to Marianne.  
  o Team to provide Marianne with the Section 4 introductory paragraph by Dec. 14.  
  o Mary & Torrey will look at possible data for a section 4 progress map by Dec. 14.  
  o Mary to look into Manuela’s data for Section 5 Table 1.  
  o Mary to provide language for Section 5 about disaster 4363.  
  o Mary to confirm whether the state is doing a THIRA and a HIRA or just a THIRA.  
  o Mary to confirm THIRA classifications (low/medium/high).  
  o Mary to invite INDOT to one of the December meetings.

**Attendees:** 12/05/2018 9-10AM

**Date:**
- Torrey Glover – IDHS
- Kisha Morris – IDHS
- Alicia Schoening – IDHS
- Kayla Swoveland – Polis
- Marianne Cardwell – Polis

Summary:

- The team discussed possible dates for meeting with INDOT. The week of January 7th worked for IDHS & Polis. Polis requested to move the usual Wednesday meeting to another day that week due to a tentative Meeting #1 with Warren County that day. IDHS will work with INDOT and send out the invitation.
- Torrey suggested inviting IU’s Environment Resilience Institute (ERI) to discuss 2019 mitigation strategies. The team thought that January 16 would work well. Torrey will invite ERI staff.
- Marianne briefly discussed the Hazus earthquake training that Kevin Mickey did for Michael Hamburger and Anna Jessee, as well as the results of using a Shakemap for the analysis. Marianne will schedule a follow-up meeting with Kevin, Michael, and Anna to discuss the analysis results and decide of the way forward.
- Marianne discussed changing the information in section 2 related to GDP and primary industries within MSAs. IDHS agreed to use employment numbers instead of industry GDP.
- Marianne requested public assistance information, especially for LaGrange County. Torrey will contact the right person at IDHS to request that information.
- Torrey asked about the status of the contract paperwork at IU. Marianne will check on the status.
- Marianne indicated that due to a very busy week, Section 2 will not be ready for review by IDHS by the end of this week and will most likely provide the draft section early next week.
- Marianne went through the previous meeting’s action items to inquire about their status.

Action Items:

- Polis:
  - Marianne to schedule a meeting with Michael, Anna, and Kevin to discuss the earthquake analysis.
  - Marianne to talk to inquire as to the status of the contract paperwork.
- IDHS:
  - Torrey to schedule a meeting with INDOT the week of 1/7/19.
  - Torrey to invite ERI staff for the 1/16/19 meeting.
  - Torrey to request public assistance information.

- Jim Sparks – Polis
- Kayla Swoveland – Polis
- Marianne Cardwell – Polis

Summary:

- **Section 2:**
  - The team briefly reviewed the draft version of section 2 that Marianne sent out on 12/11/18. A few items were noted and Marianne will fix those.
  - IDHS will provide comments to Section 2 by this Friday (12/14/18). Marianne will update the section as requested and provide a final copy to Torrey for review prior to submitting to Steve Greene.

- **Section 5:**
  - Marianne verified the numbers on Table 1 and they match the information provided by Manuela. IDHS will review the information in the table with Manuela and provide an update to Marianne early next week.
  - Marianne will sort Table 1 by date.
  - Marianne requested the language to include on page 2 for 4363.
  - Marianne requested an update on whether the state has done a new THIRA or HIRA.
  - Marianne requested an update on the language for Table 3.
  - Marianne reviewed the suggested additional language for section 5.4 and requested additional information from IDHS that would match the state’s THIRA.
  - Jim pointed out that the parcel count in Table 6 is lower than expected and could be explained by government-owned parcels. Marianne will double-check the numbers.

- **Section 4:**
  - Torrey indicated that IDHS will most likely provide the Section 4 language and content next week and that it is ok if the submittal to FEMA happens in January (vs. the planned December submittal).

- **Sections 6 & 7:**
  - Polis has started work on the flood analysis by working on the depth grids. Polis hopes to get most, if not all, of the depth grids created by the end of the year.
  - Michael Hamburger, Anna Jessee, Kevin Mickey and Marianne are meeting next week Monday to review the results of the Hazus earthquake analyses and determine which option the plan should include.
  - Marianne pointed out that the 2014 plan had very little for the hazmat section and asked if the state wanted to have more analysis in that section. Kayla suggested including a list of common chemicals that are transported through Indiana. Marianne suggested an ALOHA analysis & Kayla suggested running this analysis in 3 locations in the state. Marianne also suggested including information about the 50-mile radius around the nuclear facility in southwest Michigan.
  - Jim said that INDOT should have information on chemicals. The team will ask INDOT about chemicals going through the state.
  - Marianne asked if the state wanted to include anything specific in the tornado section. Kayla suggested including information about safe rooms. Torrey asked Kisha to send Polis the latest...
tornado map. Jim mentioned that a GIS analyst at IDHS did a detailed analysis of a tornado in Clark County using IDLGF data. Kayla suggested creating hot spot maps for tornadoes of certain intensities.

- Torrey confirmed that the team will meet on January 7 with INDOT. The team will not meet that Wednesday (1/9/19).
- Marianne suggested an additional meeting with IDNR in late January or early February to discuss 2019 mitigation strategies. Torrey will suggest Tuesday 2/5 or Thursday 2/7 to IDNR. The team will not meet on 2/6 due to a conflict with Daviess County meeting #3.
- IU’s Environmental Resilience Institute will participate in the January 16 meeting to discuss 2019 mitigation strategies.
- Marianne asked Torrey if he had clarified the need for public meetings with Steve. Torrey will follow up.
- Contract: the state has received IU’s paperwork and the contract is currently in IDOA’s hands.

**Action Items:**

- **Polis:**
  - Marianne to make updates to Section 2 as discussed during the meeting.
  - Marianne to provide Torrey an updated Section 2 for review prior to submitting to Steve.
  - Marianne to sort Section 5 Table 1 by date.
  - Marianne to double-check Section 5 Table 6 numbers.
  - Marianne to complete Section 5 Tables 5 & 6.
  - Marianne to ask INDOT on 1/7/19 about chemicals transported through the state.

- **IDHS:**
  - IDHS to review Section 2 and provide comments back to Marianne by Friday Dec. 14.
  - IDHS to provide disaster 4363 language for Section 5.
  - IDHS to confirm whether a new HIRA or THIRA was done.
  - IDHS to confirm language for Section 5 Table 3.
  - IDHS to provide additional THIRA language for Section 5.4
  - IDHS to provide Marianne with the Section 4 introductory paragraph by the week of Dec. 21.
  - IDHS to update 2014 strategies by the week of Dec. 21.
  - Mary & Torrey will look at possible data for a section 4 progress map by the week of Dec. 21.
  - IDHS to look into Manuela’s data for Section 5 Table 1.
  - Torrey to determine what is needed in terms of public meetings for the state plan.
  - Kisha to send the latest tornado map to Polis.

**12/19/2018**

**Time:** 9-11AM

**Attendees:**
Summary:

- Section 4:
  o Marianne inquired as to the status of IDHS’ review of the 2014 mitigation strategies. IDHS stated that this will be completed in January.

- Section 5:
  o The team reviewed Section 5 and IDHS provided feedback on a number of items. Marianne will make the requested updates and provide to Torrey this afternoon. Torrey will review and let Marianne know if the section can be submitted to FEMA this week.

- Section 6:
  o The team reviewed the earthquake scenarios provided by Michael Hamburger (Indiana University). IDHS will review the proposed scenarios in more detail and confirm their usage in early January.
  o Marianne explained progress and remaining questions on using ShakeMaps instead of using arbitrary scenarios in Hazus along with Polis-provided soil and liquefaction data. Kevin Mickey will research this further and reach out to USGS & FEMA staff to inquire as to the right way to develop the ShakeMaps for use within Hazus. Mary stated a preference for using ShakeMaps.
  o Mary would like Polis to add text to emphasize that Hazus is a planning tool and not a response tool.
  o Marianne will reach out to Allison Curry to inquire about Indiana faults and historic earthquake maps.
  o Mary will look into the 2008 earthquake to provide historic information in the plan.

- The team agreed to cancel the January 2nd meeting as this is the first day back from the holidays.

- Contract: the state has send the contract to IU.

Action Items:

- Polis:
  o Marianne to make updates to Section 5 as discussed during the meeting.
  o Marianne to provide Torrey an updated Section 5 for review prior to submitting to Steve.
  o Marianne to reach out to Allison Curry to inquire about Indiana faults and earthquakes maps.
  o Polis to add language to the plan to emphasize that Hazus is a planning tool, not a response tool.

- IDHS:
  o IDHS to review Section 5 and provide comments back to Marianne by Friday Dec. 21.
  o IDHS to provide Marianne with the Section 4 introductory paragraph by the week of Dec. 21.
  o IDHS to update 2014 strategies by January 4.

Date: 12/19/18
- Torrey Glover – IDHS
- Mary Moran – IDHS
- Alicia Schoening – IDHS
- Tom Vanderpool – INDOT
- Lyle Sadler – INDOT
- Jim Sparks – Polis
- Marianne Cardwell – Polis

Summary:

- IDHS & Polis met with INDOT representatives to obtain their input on the plan:
  - INDOT has a GIS layer that tracks about 200 known or potential landslides that can impact its infrastructure. INDOT will provide this information to Polis.
  - INDOT recently had its Infrastructure Protection Report updated. It lists structures, such as bridges, that need additional protection. The report looks at earthquakes. I-69 would be impacted by earthquakes and/or liquefaction. The report is confidential but INDOT will provide Polis with the title and executive summary so that it can be referenced in the plan.
  - INDOT has an underground coal mines layer which also includes quarries. INDOT is interested in where those intersect roads. Jim will reach out to Jeff Motz at INDOT for a copy of that layer.
  - Tom will meet with the INDOT hydrology section to see if the fluvial erosion hazard section needs to be updated.
  - In terms of earthquakes, there are 3 different design standards for corridors where the military could have convoys. INDOT took the middle design standard for I-69.
  - In terms of terrorism, additional bridges provide redundancy in case one bridge is destroyed.
  - INDOT inspects all airports, including pavement condition, encroachment, and airspace penetrations.
  - From a discussion about hazardous materials, Tom mentioned that the state police (motor carrier section) or DOA may manage a map of hazmat routes. The team should look into the shipment of radioactive materials as well.
  - In case of drought or wildfire, INDOT provides transportation of water for DNR to mitigate wildfires. Tom will write a paragraph on what INDOT almost did during the last significant drought in the state.
  - After storms, INDOT will take a dump truck with the necessary equipment to clear roads. There isn’t much more that INDOT can do to prevent debris in the roads as these debris typically come from outside of the right-of-way. Tom will provide a map of priority routes.
  - INDOT is planning on improving its maintenance of right-of-ways in the future, including by recording videos from drones of right-of-ways to identify problem areas.
  - INDOT currently has 4 drones but may want to buy more for emergency response, right-of-way clearance, and flood documentation. This should be added to the list of future mitigation strategies and should include training.
  - INDOT would like to install additional stream gages for better tracking of rivers.

- Section 4:
  - IDHS is still working on this section and hopes to complete it by 1/18/19.

- Section 8:
  - The team reviewed the draft section 8. Alicia will provide additional information for the terrorism section, include language about the Fusion Center.
Action Items:

- Polis:
  - Reference the Infrastructure Protection Report in the plan.
  - Jim to reach out to Jeff Motz at INDOT for the following data layers: bridges, sinkholes, facilities inventory.
  - Polis to reach out to State Police and/or DOA to inquire about a map of hazmat routes.
  - Include a future strategy for acquisition of drones and related training, installation of additional stream gages.
  - Marianne to reach out to Matt Riggs (Polis) for the latest fluvial erosion/mobile streams map.
  - Jim to check with Matt Riggs (Polis) about transportation vulnerability studies at the county level.
  - Marianne to send out the 2014 mitigation strategies to INDOT.

- IDHS:
  - Provide section 4 to Polis by 1/18/19.
  - Alicia to provide additional information for Section 8’s terrorism portion, include language about the Fusion Center.

- INDOT:
  - Provide Polis with landslide GIS layer.
  - Provide Polis with title and executive summary of recent Infrastructure Protection Report.
  - Tom to meet with hydrology section to see if the fluvial erosion hazard section needs to be updated.
  - Tom to write a paragraph on what INDOT almost did during the last significant drought in the state.
  - Tom to provide a map of priority routes.
  - Review INDOT verbiage from 2014 plan (9.1.3).

State of Indiana – Standard Multi-Hazard Mitigation Plan Meeting

Date: 1/16/19

Time: 9:00 - 11:00 AM
Summary:

- The team reviewed last meeting’s action items and provided an update on their status.

- Section 4:
  - IDHS is still working on this section and hopes to complete it by 1/18/19.

- Section 8:
  - The team reviewed Section 8 submitted to IDHS last week and provided comments.
  - IDHS has received information from the Fusion Center but will provide a summary of this information to Polis for inclusion in this section.
  - Polis shared statistics received from Tad Stahl at the State’s IOT. The team agreed to include some of those statistics in the Cyber Attack subsection.
  - Torrey pointed out a sentence in the introduction that should be updated. Polis will update accordingly.

- Section 1:
  - The team reviewed Steve Greene’s (FEMA) comments on Section 1.
  - Torrey will review the language on page 2 with Mary and others at the state.
  - Torrey will review the funding numbers on pages 3, 4.
  - Marianne will make the rest of the updates as requested by Steve, except for the first 12th comment. For those, she will explain why to Steve.
  - Marianne will update Table 2 by removing the November 2007 row and updating the table label.

- Section 2:
  - The team reviewed Steve Greene’s comments on Section 2. The Section was accepted as is and does not require any changes.
  - Polis will make sure to address the impact of climate change on select hazards in Sections 6 and 7.

- Section 5:
  - The team reviewed Steve Greene’s comments on Section 5.
  - When providing Steve with the updated section, Marianne will explain why 2018 data was not included.
  - Torrey will provide $ breakdown for Steve’s 1st comment.
  - Torrey to provide additional information addressing the 2nd comment.
  - Polis to update the text as requested in the 3rd comment.
  - The team agreed to keep severe thunderstorms and tornadoes in the same subsection and Marianne will explain the reasoning to Steve when submitting the updated section.
  - Polis will fix the typo on page 3.

- Section 6:
  - The team went over select portions of Section 6 of the 2014 plan to discuss data needs and display options.
  - Polis will include the NFIP and RiskMAP information in the flood section of section 6.
o Torrey will provide Polis with the repetitive and severed repetitive loss information (counts by county and payments by county).
  
o Torrey will provide Polis with the buy-out information by county.
  
o Polis will change Table 21 and Figure 48 in the 2014 plan to show the data by county.
  
o Polis will reach out to Anita Vance and Darren Pearson for NFIP data.
  
o Polis will change the tornado scenario to the Evansville tornado of November 2005. Torrey will provide language on storm shelters based on Evansville and Washington County.

- Public Meetings:
  o The team discussed public meetings. Torrey will follow-up with Steve to confirm that public meetings are required. Marianne suggested the week of March 11 and March 18 as potential days for these public meetings.
  
o The team discussed having from 1 to 3 meetings, but this will depend on Steve’s input.
  
o The team discussed potentially providing an online survey for the public to provide feedback on the plan. Polis will send an example to IDHS for review.

- 2019 Strategies:
  o The team discussed whether to have additional meetings with stakeholders for new strategies or whether to have an online form available to stakeholders. The consensus after discussion was to provide an online form to stakeholders, including Silver Jackets, review the feedback, and then schedule follow-up discussions as needed.
  
o Torrey asked Marianne to present this to the Silver Jackets at tomorrow’s meeting (January 17) or assist Mary if Mary can attend.

- Schedule:
  o Due to a conflict, the February 6 meeting is to be moved to February 5. Polis will reserve its large conference room in case no meeting rooms are available at the State.
  
o Marianne indicated she will be out of the country Thursday March 27 through Friday April 5.
  
o Due to large amounts of data processing, Polis requested to delay the submittal of Section 6 to later in February. IDHS agreed.

Action Items:

- Polis:
  o Update Section 8 and provide to IDHS for final review prior to submittal to FEMA.
  
o Update Section 1 as requested by FEMA and confirmed by IDHS. Provide to IDHS for final review prior to submittal to FEMA.
  
o Address impact of climate change on select hazards in sections 6 and 7.
  
o Update Section 5 as requested by FEMA and confirmed by IDHS. Provide to IDHS for final review prior to submittal to FEMA. Explain to FEMA why 2018 data was not included. Also explain why severe thunderstorms and tornadoes will be kept together.
  
o Include NFIP and RiskMAP information in section 6.
  
o Change Table 21 and Figure 48 in the 2014 plan to show the data by county.
  
o Reach out to Anita Vance and Darren Pearson for NFIP data.
  
o Change the tornado scenario to the Evansville tornado of November 2005.
  
o Send example survey to IDHS.
  
o Move 2/6 meeting to 2/5.

- IDHS:
  o Provide Section 4 to Polis by 1/18/19.
  
o Provide Fusion Center summary to Polis by 1/18/19.
  
o Review a number of FEMA’s comments in Section 1 and provide the information to Polis.
- Review a number of FEMA’s comments in Section 5 and provide the information to Polis.
- Provide Polis with repetitive and severed repetitive loss information (counts by county and payments by county).
- Provide Polis with buy-out information by county.
- Torrey will provide language on storm shelters based on Evansville and Washington County.
- Torrey to follow up with Steve to confirm public meeting requirements.

The team reviewed last meeting’s action items and provided an update on their status.

Section 6:
- NFIP repetitive loss data: Torrey provided Marianne with information on repetitive loss for the state, which comes straight from FEMA Region 5. Marianne to verify what information she still needs from Darren Pearson for Section 6.
- Tornado: Kisha will send Polis a map of the Vanderburgh County tornado path.

Section 7:
- Low-head dams: Torrey indicated it was ok to condense the low-head dam information provided by Manuela.
- Marianne asked if the plan should mention the North Indy levee work. IDHS agreed.

Section 9:
- The team discussed the online survey for obtaining new mitigation strategies. Since Google Forms is blocked for most state employees, Marianne working with IOT to redo the form in SurveyMonkey. IDHS will use just the SurveyMonkey version.
- Polis should remove the severe repetitive loss information from section 8.3.
- Torrey to determine whether there are any rankings for communities & counties.
- For section 8.4, replace CAPI rankings with something similar to at-risk populations. Polis to think of categories for the table.
- Sections 8.5 & 8.6: new text should discuss funding mechanisms and include a summary of participating counties and their last update date. Torrey to provide language on funding mechanisms and Alicia to send list of counties and their status.

Section 10:
- The team reviewed the original section 8 (Local Capabilities to Mitigate Hazards) to identify changes or data needs.
- Torrey to ask Mary for contacts within departments listed in 2014 plan section 9 to update language for each agency. The deadline for the text update is 2/15/19.
- Torrey to confirm the data in Table 51.
- State facilities: Torrey to follow-up with Mary on the two groups that would provide additional state facility information.
- 2/5 meeting to be held at state. Kisha to send Marianne room information.

Action Items:
- **Polis:**
  - Marianne to verify that the NFIP repetitive loss information she received from Torrey contains the necessary information.
  - Marianne to update Darren Pearson on needed NFIP information.
  - Marianne to condense low-head dam text.
  - Marianne to include North Indy levee work in Section 7.
  - Polis to remove severe repetitive loss information from section 8.3 (original).
  - Polis to come up with categories for the table in the original section 8.4.

- **IDHS:**
  - Kisha to send Polis map of Vanderburgh County tornado path.
  - Torrey to send SurveyMonkey information to plan participants.
  - Torrey to determine whether there are rankings for communities & counties.
  - Torrey to provide language on funding mechanisms.
  - Alicia to provide list of counties and their status.
  - Torrey to ask Mary for contacts within departments listed in 2014 plan section 9 to update language for each agency. The deadline for the text update is 2/15/19.
  - Torrey to review section 9.2.
  - Torrey to confirm the data in Table 51.
  - Torrey to follow-up with Mary on groups that would provide additional state facility information.
  - Kisha to send Marianne meeting room information for 2/5.

01/30/2019

Time: 9:00-10AM (Virtual Call via Zoom)

Attendees:
- Torrey Glover – IDHS
- Mary Moran – IDHS
- Alicia Schoening – IDHS
- Kisha Morris – IDHS
- Marianne Cardwell – Polis
- Kayla Swoveland – Polis
- Jim Sparks – Polis

Summary:
- Today’s meeting was held virtually due to sub-zero temperatures in Indianapolis and all participants working from home.
- The IDHS team was very busy this week working on grant applications and should have more time in the next week to focus on the state plan.
- The team reviewed last meeting’s action items.
  - Mary & Torrey will look for the repetitive loss code meaning in the spreadsheet that Torrey sent to Marianne last week.
  - Torrey will send Marianne the buy-out information.
  - Torrey will send out the SurveyMonkey URL by Tuesday.
  - Torrey will look into potential rankings for the community listing in section 8 of the 2014 plan.
  - Alicia will redo the list of counties and status.
  - Mary will update Section 9 of the 2014 plan language.
  - Torrey & Mary will review the language in Section 9.2 of the 2014 plan with the relevant agencies.
  - Torrey will send out the new table that will replace Table 51 of the 2014 plan.
  - Mary found an email she had sent to Brian Renner in regards to state facilities and will follow up. Jim indicated that Mike Martin at IDNR may have some state facility information. Mary will reach out.
  - Torrey will provide any additional comments to Marianne, after which Marianne will resubmit to IDHS for final review prior to submittal to FEMA.
- The team discussed how to include the impact of climate on the hazards. Mary and Torrey will discuss and provide their feedback during the next meeting.
- Marianne indicated that 90% of the analysis for Section 6 (Natural Hazards) has been run and Polis has started working on the text. Due to the size of this section, the team agreed to review it in chunks.
- The team discussed how best to incorporate confined feeding operations and coal ash sites in the plan. After reviewing FEMA’s requirements, Mary thinks that it may be best not to include it but to consider including it in the next version of the plan. Torrey will confirm.

**Action Items:**

- **Polis:**
  - Marianne will add language to low-head dams to indicate that the number fluctuates as more are found or removed.
  - Marianne will update the legend of Figure 3 of Section 7 to say “Known” low head dams.
  - Marianne will add a map of non-levee embankments to Section 7.
  - Marianne is expecting additional language from Michael Hamburger on the landslide section (Section 7).
  - Marianne will add language about the 1963 Coliseum and 1968 Richmond explosions to Section 7.
  - Marianne to submit Section 6 in chunks to IDHS for review.

- **IDHS:**
  - Mary & Torrey will look for the repetitive loss code meaning in the spreadsheet that Torrey sent to Marianne last week.
  - Torrey will send Marianne the buy-out information.
  - Torrey will send out the SurveyMonkey URL by Tuesday.
  - Torrey will look into potential rankings for the community listing in section 8 of the 2014 plan.
  - Alicia will redo the list of counties and status.
  - Mary will update Section 9 of the 2014 plan language.
  - Torrey & Mary will review the language in Section 9.2 of the 2014 plan with the relevant agencies.
  - Torrey will send out the new table that will replace Table 51 of the 2014 plan.
  - Mary will reach out to various state agencies for state-owned facilities.
  - Torrey will send feedback on the sections reviewed by Steve in the next couple of days.
  - Mary and Torrey will discuss inclusion of effects of climate change on hazards and provide their feedback during the next meeting.
  - Torrey will confirm whether to include a section on confined feeding operations and coal ash sites.

</table>
02/05/2019

Time: 9:00-11AM

Attendees:
- Torrey Glover – IDHS
- Alicia Schoening – IDHS
- Kisha Morris – IDHS
- Marianne Cardwell – Polis
- Kayla Swoveland – Polis
- Jim Sparks – Polis

Summary:
- Section 7:
  o Torrey provided a couple of additional changes to Marianne’s latest update. After making those changes, Marianne should submit the section to Steve and copy Torrey.
- IDHS requested that Polis send the IDHS team a list of prioritized action items.
- Section 4:
  o The team discussed the approach for section 4. IDHS is currently planning on writing a narrative for those 2014 strategies that have been completed, then indicate that strategies that are in process or have not yet been started are in the new strategy table.
  o Mary is currently writing the narratives for completed strategies.
- Section 6:
  o The team discussed the order of the natural hazards in Section 6. Marianne suggested include subsidence after earthquakes as it may flow better. The team also discussed moving extreme temperatures before drought. The IDHS team will discuss and follow-up with Polis.
  o Marianne will send a draft landslide section to Torrey.
  o Earthquakes – Jim suggested adding an additional secondary effect related to disruption of services. The team agreed.
  o Flood:
    ▪ The team discussed whether or not to show a map showing $ loss and loss ratio by counties. The team agreed that Polis should map both and then the team can determine which one to include.
  o Summer storms:
    ▪ This section should discuss derechos.
    ▪ Kisha to find a representative image of derechos and provide a narrative to Polis.
  o Wildfire:
    ▪ Kisha & Alicia have written event narratives that Torrey is currently reviewing. Torrey will send to Polis upon review.
    ▪ The team discussed whether to include agricultural field fires. This could potentially be included in the drought section.
  o Marianne to ask Steve whether he would like section 6 provided to him in chunks for easier review.
- Section 9:
  o Torrey will send the SurveyMonkey survey today.
- Public Meetings:
• The team discussed public meetings and decided to have one in the morning and one in the afternoon (on the same day) at the state building the week of March 11.
• IDHS will reserve a room for the public meeting.

**Action Items:**

- **Polis:**
  • Marianne to finalize Section 7 draft and submit to FEMA.
  • Marianne to send prioritized action items list to IDHS.
  • Marianne to send the draft landslide section to Torrey.
  • Jim to write an additional earthquake secondary effect focused on disruption of services.
  • Kayla to create maps showing flood loss and loss ratio by county.
  • Marianne to ask Steve if he would prefer to receive Section 6 in smaller chunks.
- **IDHS:**
  • IDHS to confirm order of natural events in Section 6.
  • Kisha to write a derecho narrative and provide a representative image to Polis.
  • Torrey to provide reviewed wildfire event narratives to Polis.
  • Torrey to send the SurveyMonkey URL today.
  • IDHS to reserve a meeting room for a full day the week of March 11.

02/13/2019

Time: 9:00-11AM

Attendees:
- Mary Morrán – IDHS
- Torrey Glover – IDHS
- Alicia Schoening – IDHS
- Kisha Morris – IDHS
- Marianne Cardwell – Polis
- Kayla Swoveland – Polis

Summary:
- Sections 1 (Introduction) and 5 (Risk Assessment Overview): IDHS will provide information to finalize these sections (in response to Steve Greene’s comments) after we have submitted the rest of the plan to Steve.
- Section 4 (2014 Strategies Progress): Mary is working on this section.
- Section 5 (Risk Assessment Overview):
  - Polis to add information about state facilities.
  - IDHS to send Polis information about IDHS facilities.
- Section 6.1 (Natural Hazards – Flood):
  - Mary will provide a map of the 2018 flood.
  - Polis will include language on Hazus analysis and user-defined buildings, along with how flood depth grids were created.
  - Polis to remove CAPI in 6.1.2, but add Hazus along with analysis of repetitive and severe repetitive losses.
  - Polis to relabel Hazus-related maps & tables to “Projected”.
  - Torrey is still working on the buy-out information and will send it to use as soon as he’d been able to go through it.
- Section 6.3 (Earthquakes):
  - Polis to relabel Hazus-related maps & tables to “Projected”.
  - Building code: Polis to remove yellow line on page 52.
  - Indy scenario: Polis to rephrase to Central Indiana as this is more appropriate.
  - Marianne to send updated version to Torrey for review prior to submitting to Steve.
- Section 6.6 (Winter Storm):
  - Polis to fix typos on page 2.
  - Marianne to update the dates at the bottom of page 2. Mary to send dates to Marianne.
  - Polis to add word on page 4.
  - Marianne to send updated version to Torrey for review prior to submitting to Steve.
- Section 6.7 (Ground Failure):
  - Marianne to fix Figure 12.
  - Marianne to send updated version to Torrey for review prior to submitting to Steve.
- Section 6.8 (Wildfire):
  - Mary may provide text from a California study on wildfires for 6.8.2. If no relevant text, remove this section.
  - Marianne to send updated version to Torrey for review prior to submitting to Steve.
- **Section 6.9 (Disease Outbreak):**
  - Marianne to remove 6.9.2.
  - Marianne to send updated version to Torrey for review prior to submitting to Steve.

- **Section 9 (Mitigation Strategies):**
  - 2019 mitigation strategies will indicate whether they were also in the 2014 plan.
  - The team may add language saying that these strategies are never completed and will always be ongoing.

- **Public meetings:**
  - The State will release two press releases. The first will inform the public that a draft plan and a public meeting will be held. The second release will provide a link to the plan (hosted on state website) and the survey for providing feedback.
  - This process should be described in Section 3 and can be edited after the meetings have taken place as needed.
  - Public meetings will be held at the State building at 10AM and 2PM on March 14. Torrey will put together the presentation and will present. The presentation should take approximately 15 minutes.

**Action Items:**

- **Polis:**
  - Include language on Hazus analysis and user-defined buildings, along with how flood depth grids were created.
  - Polis to remove CAPI in 6.1.2, but add Hazus along with analysis of repetitive and severe repetitive losses.
  - Polis to make requested changes to sections 6.3, 6.6, 6.7, 6.8 and 6.9, then provide to Torrey for final review prior to submitting to FEMA.
  - Polis to add information about state facilities in section 5.

- **IDHS:**
  - Mary to provide a map of the 2018 flood.
  - Mary to provide text from California study for wildfires.
  - Mary to send winter storm dates to Marianne.
  - IDHS to send Polis information about IDHS facilities.

- **General:**
  - Team to add language saying that mitigation strategies are never completed in Section 9.

02/20/2019

Time: 9:00-11AM

Attendees:
- Mary Morran – IDHS (via phone)
- Torrey Glover – IDHS
- Alicia Schoening – IDHS
- Kisha Morris – IDHS
- Marianne Cardwell – Polis
- Kayla Swoveland – Polis

Summary:
- Section 6:
  - The team’s goal is to submit the rest of the subsections to Steve by the end of this week.
  - Subsection 6.4 – Extreme Temperatures:
    - IDHS provided input on a couple of changes that need to be made to this section, including confirming the source of a couple of statements made in the text. Marianne to follow-up with Torrey, make changes as necessary, and submit a final draft to Torrey for review prior to sending to FEMA.
  - Subsection 6.2 – Severe Weather:
    - Torrey to send additional language for the Palm Sunday tornado outbreak.
    - Kisha to send a tornado map of the super outbreak.
    - Marianne to update as necessary and submit a final draft to Torrey for review prior to sending to FEMA.
  - Subsection 6.1 – Flood:
    - IDHS is still reviewing and will provide feedback by Friday.
    - This section should include language on how the state deals with repetitive loss properties.
    - Marianne to update as necessary and submit a final draft to Torrey for review prior to sending to FEMA.
- Section 9 – Mitigation Strategies:
  - Marianne to reach out to IOT to obtain initial SurveyMonkey results by Tuesday so that the team can do an initial review during next week’s meeting.
- Section 10 – Local Capabilities:
  - The team reviewed a draft of Section 10.
  - Mary will reach out to Ashley to see if there is an existing map that shows buyouts in the state.
  - Explain that the state used to focus almost exclusively on buyouts in the past, but that mitigation has changed in the past five years.
  - Both Polis & IDHS will look at the FEMA guide to see if local strategies need to be included in the plan.
  - Marianne to send an updated draft to IDHS.
- Section 11 – State Capabilities:
  - Torrey to inform Polis on the titles of sections 10 and 11 (ex: “Local Capabilities” vs. “Local Capabilities to Mitigate Hazards”).
  - Polis to fix missing header/footer.
- Marianne to send an updated draft to IDHS.

- **Section 12 – Plan Maintenance, Monitoring, and Evaluation:**
  - Polis to fix missing header/footer.
  - Polis to review FEMA requirements and provide some suggestions by Friday for what to include in this section.

- **Executive Summary:**
  - Potentially mention at there is an increased awareness of the benefits of mitigation at the local level.

- **Section 7 – Technological Hazards:**
  - Marianne showed information received in the past week in regards to levees. Polis should wait until FEMA provides feedback on the section prior to including levee information. It could be added to the NLE map.

- **Section 3:**
  - The team looked over the list of plan participants. Polis to add Manuela to the list.
  - IDHS to review the list and provide additional names & correct any inaccurate titles for IDHS staff.
  - Marianne to reach out to other participants to confirm titles and agency names.
  - Marianne to send draft to IDHS.

- **Section 4:**
  - IDHS has completed the table and will be working on the introductory paragraph this week.

- Marianne stated that her goal was to submit everything but Section 9 to FEMA by the end of next week (3/1/19).

- Marianne to tell Michael Hamburger that we need strategies by this Friday.

- **Meeting schedule:**
  - Due to a conflict for Polis staff, move the 3/6 meeting to Monday 3/4 from 8:30AM to 11AM. Kisha to confirm room.
  - The team will also meet on Friday 3/8 from 9 to 11AM. Kisha to confirm room.

- **Appendices:**
  - Polis to confirm what needs to be included in the appendices.

**Action Items:**

- **Polis:**
  - Marianne to update Subsection 6.4 and send to Torrey for review.
  - Marianne to update Subsection 6.2 and send to Torrey for review.
  - Marianne to update Subsection 6.1 and send to Torrey for review.
  - Marianne to reach out to IOT for SuveyMonkey results by Tuesday.
  - Marianne to add Manuela to the list of plan participants and then share the spreadsheet with IDHS.
  - Marianne to send drafts of Sections 10, 11, 12, and 3 to IDHS for review.
  - Marianne to reach out to non-DHS plan participants to confirm titles & agency names.
  - Marianne to inform Michael Hamburger that strategies are needed by this Friday.
  - Marianne to send updated meeting invitations.
  - Polis to fix missing header/footer in Sections 11 & 12.
  - Polis to look at FEMA guide to see if local strategies need to be included in plan.
  - Polis to review FEMA requirements for Section 12 and provide suggestions of what to include by Friday 2/22/19.
- Polis to confirm what needs to be included in appendices.

IDHS:
- Torrey to send additional Palm Sunday tornado outbreak to Marianne.
- Torrey to provide language on how the state deals with repetitive loss properties for Subsection 6.1.
- Torrey to confirm titles of Sections 10 and 11.
- Kisha to send super outbreak tornado map to Marianne.
- Kisha to reserve meeting rooms for 3/6 & 3/8 meetings.
- Mary to reach out to Ashley for a buy-out map.
- IDHS to provide Subsection 6.1 feedback to Polis by Friday 2/22/19.
- IDHS to add language to Section 10 discussed ow state used to focus almost exclusively on buyouts in the past but that it has changed in past 5 years.
- IDHS to look at FEMA guide to see if local strategies need to be included in plan.
- IDHS to review plan participants list and confirm titles of IDHS staff.
- IDHS to provide language for Section 4.

02/27/2019

Time: 9:00-11AM

Attendees:
- Mary Morran – IDHS
- Alicia Schoening – IDHS
- Kisha Morris – IDHS
- Jim Sparks – Polis
- Marianne Cardwell – Polis
- Kayla Swoveland – Polis

Summary:
- County plans:
  - Decatur: Polis has not heard back from Decatur in a month and asked IDHS whether they knew of any issues at the county. Kayla will send the list of information that Polis still needs to wrap up the plan to Alicia and Alicia will reach out.
  - Tipton: Alicia to reach out to Tipton County to explain how to do the drawdown of funds.
  - Clinton: Polis still has not heard back from Clinton County. The team agreed to give them a deadline of end of March to start working on the plan in order to get it done by end of October.
  - Jasper: Alicia will reach out to Jasper County.

- Section 4:
  - Mary has updated all of the 2014 strategies. Torrey will review and send to Marianne.
- Section 11:
  - Mary has reviewed and updated the draft. Torrey will review and send to Marianne.
- Section 10:
  - Indiana is a home rule state. The state can recommend but not mandate. Land use is determined at the local level, not the state level. EMAs are included in the process/discussions. Marianne to move the “Policies regulating development” paragraph from the 2014 plan (page 175) to Section 10.2 and reword/expand as necessary.
  - Mary & Torrey to review section 10.1.
- Section 12:
  - Torrey to provide updated table 46.
  - IDHS to provide feedback to Marianne.
- Section 3:
  - Jim to provide sentence thanking Silver Jackets for help with the plan. Marianne to add.
  - Mary to reach out to PIO to ensure all 92 EMAs are informed about the draft plan. She will also ask who gets the gov delivery info. Mary to provide language related to this. Marianne to add this to the press release information in Section 3.
- Section 1:
  - Marianne started updating this section based on Steve’s feedback. The team reviewed a few items that were not fixed. Mary provided info on two of them. Mary will look into the funding numbers discrepancy and get back to Marianne.
  - Marianne to send Steve’s email to Mary.
- 2019 Mitigation Strategies:
  - Marianne to forward Michael’s email to the team.
- IDHS to review submitted strategies and identify the 2014 strategies that should be kept.
- IDHS and Polis to conduct crosswalks and provide results during Monday’s meeting.
- Mary to confirm with Torrey that we will not submit remaining sections individually to FEMA but rather provide a full draft.

Action Items:

- **Polis:**
  - Kayla to send needed information from Decatur to Alicia.
  - Marianne to reach out to Clinton County and explain timeline.
  - Marianne to add home rule state language to section 10.2.
  - Jim to provide sentence to Marianne thanking Silver Jackets for help with the plan.
  - Marianne to add gov delivery info to section 3.
  - Marianne to make requested changes to section 1.
  - Marianne to forward Michael’s email to the team.
  - Marianne to send Steve’s email to Mary.
  - Polis to conduct crosswalk by Monday.

- **IDHS:**
  - Alicia to reach out to Decatur.
  - Alicia to reach out to Tipton County to explain funds drawdown procedure.
  - Alicia to reach out to Jasper County.
  - Torrey to review 2014 strategies and send Section 4 to Marianne for inclusion.
  - Torrey to review Mary’s edits to section 11 and send to Marianne for inclusion.
  - Mary & Torrey to review section 10.1 and provide feedback to Marianne.
  - Mary to reach out to PIO to ensure all 92 EMAs are informed about the draft plan.
  - Mary to obtain list of recipients of gov delivery info from PIO.
  - Mary to provide language related to gov delivery to Marianne.
  - Mary to look into the Section 1 funding discrepancy and provide info to Marianne.
  - Mary to confirm with Torrey that we will not submit remaining sections individually to FEMA but rather provide a full draft.
  - IDHS to conduct crosswalk by Monday.
  - Torrey to provide updated table 46 (Section 12).
  - IDHS to provide Section 12 feedback to Marianne.

03/04/2019

Time: 8:30-11AM

Attendees:
- Mary Morran – IDHS
- Torrey Glover - IDHS
- Alicia Schoening – IDHS
- Marianne Cardwell – Polis
- Kayla Swovel – Polis

Summary:
- The team reviewed FEMA’s comments on Section 6.
  - General comments:
    - State-owned properties: the team discussed options for covering state-owned properties and decided to use the INDOT facility locations and provide an explanation that no statewide dataset was available for the team to use that covers all state-owned properties.
    - Local vulnerability: Marianne will add a paragraph to each natural hazard with a local and state perspective. The team reviewed rankings for each natural hazard. Marianne to review this ranking with figure 40.
    - Change in development: Marianne suggested doing what Polis does for the county plans, which includes querying the IDLGF data for new construction since the last plan. The team agreed to this approach. Polis will perform the query, create a hot-spot map and an overlay map with SFHA data. This information will be added to Section 10.4. The table in that section will get an additional column indicating the top 5 counties with changes.
  - Severe weather:
    - Comment 2: explain that the analysis was produced with better and more recent data.
    - Comment 3: Marianne to investigate.
  - Earthquakes: Marianne to either add a paragraph explaining what the columns mean or, provide different, more intuitive data that can be summed for all facilities.
  - Winter storm:
    - Comment 1: add “Enhanced”.
    - Comment 2: add reference to the NCDC Climate Regions figure in the first sentence of the first paragraph under the table in 6.6.1.2.
  - Wildfire:
    - Comment 1: Mary to reach out to IDNR regarding this comment.
    - Comment 3: Marianne to remove the second sentence of 6.8.2 and replace it with the sentence from 6.5.1.
- Section 3:
  - Torrey to update subsection 3.3.
  - Torrey to provide reviewed section to Marianne by 3/5/19.
  - Marianne to change “17 agencies” to “multiple agencies”.
- Section 4:
  - Torrey to send language to Marianne by 3/5/19.
- Mary to provide paragraph on how hazard mitigation is never completed.
  - Section 9:
    o Marianne to request latest surveys from IOT.
    o Marianne to put together section 9, combining similar strategies for different hazards.
  - Section 10:
    o Torrey to review and provide to Marianne by 3/7/19.
    o IDHS should note S13, S14, and S16 of the review guide when working on Section 10.
  - Section 11:
    o Torrey will provide the reviewed section to Marianne today.
  - Section 12:
    o Reference to ISHMC should be removed.
    o Marianne to remove sentences identified during the meeting.
    o Torrey to review section 12 and send to Marianne by 3/7/19.
  - Executive summary:
    o Marianne to let FEMA know that this will be provided by end of March once all IDHS executives have had a chance to review the draft plan.

**Action Items:**

- **Polis:**
  o Polis to use INDOT facilities for state-owned properties analysis and include results in plan.
  o Marianne to add a paragraph to each natural hazard with a local and state perspective for vulnerability assessment.
  o Marianne to query IDLGF data to identify changes in development and add maps + text to Section 10.4.
  o Marianne to change facility damage tables for earthquakes.
  o Marianne to make identified changes or responses to severe weather.
  o Marianne to make identified changes to winter storm.
  o Marianne to make identified changes to wildfire.
  o Marianne to change 17 agencies to multiple agencies in section 3.
  o Marianne to request latest survey results from IOT.
  o Marianne to put together section 9 and provide to IDHS for review.
  o Marianne to remove sentences identified in section 12.
  o Marianne to let FEMA know that this will be provided by end of March once all IDHS executives have had a chance to review the draft plan.

- **IDHS:**
  o Mary to reach out to IDNR regarding comment 1 of wildfire subsection.
  o Mary to provide paragraph on how hazard mitigation is never completed for Section 4 by 3/5/19.
  o Torrey to update subsection 3.3 and provide language to Marianne by 3/5/19.
  o Torrey to provide Section 4 language to Marianne by 3/5/19.
  o Torrey to review and provide text for section 10 to Marianne by 3/7/19.
  o Torrey to provide reviewed section 11 to Marianne by 3/4/19.
  o Torrey to provide reviewed/edited section 12 to Marianne by 3/7/19.

3/27/2019

Time: 9AM-10AM

Attendees:
- Mary Moran – IDHS
- Torrey Glover - IDHS
- Alicia Schoening – IDHS
- Jim Sparks – Polis
- Kayla Swoveland – Polis

Summary:
- The team reviewed comments provided by Michael Hamburger
  - In advance of the meeting, Marianne had gone through to mark which comments were easy
    fixes and which comments required discussion from the group.
  - The team spent the hour reviewing comments and making edits to the plan where needed.
- The team then decided to hold off on meeting on the 3rd of April unless comments on the plan were
  submitted by FEMA before said time.
- The next regularly scheduled meeting will be held on 4/10/19.

Action Items:
- Polis:
  - Make indicated edits to the state plan based on feedback from IDHS
- IDHS:
  - None

4/10/2019

Time: 9AM-11:30AM

Attendees:
- Mary Moran – IDHS (via phone)
- Torrey Glover - IDHS
- Alicia Schoening – IDHS
- Kisha Morris – IDHS
- Marianne Cardwell - Polis
- Jim Sparks – Polis
- Kayla Swoveland – Polis

Summary:
- The team reviewed FEMA’s comments and discussed responses and/or edits. Polis to update the plan to incorporate all changes discussed during the meeting.
- Torrey will send Polis his notes on the comments to incorporate into the response to FEMA.
- The team reviewed Michael Hamburger’s suggested future strategies and made edits as deemed necessary. Polis to update the strategies accordingly.
- The team agreed to extract the top 2 or 3 mitigation strategies from each county plan that is active as of 12/31/2018. Polis will extract those from plans it wrote. IDHS will work with Burke to get strategies from plans it wrote. IDHS will get strategies from plans written by other contractors or counties.
- The team discussed submission to FEMA. The goal is to submit by Friday 4/12. Polis will make all changes discussed during the meeting and provide an interim copy to IDHS for review. In the meantime, IDHS will work on additional language and responses and provide those to Polis by Thursday. If time is available, IDHS will review the updated plan on Friday prior to Polis submitting to FEMA. If time is not available, Polis will submit the plan directly to FEMA.
- The team discussed the adoption of the plan. IDHS presented the draft plan to the governor’s office and the governor is ready to adopt the plan as soon as it is approved pending adoption by FEMA.

Action Items:
- Polis:
  - Update the plan to incorporate all changes discussed during the meeting.
  - Write draft response to FEMA.
  - Update future strategies based on feedback during the meeting. Inform Torrey of final number of mitigation strategies to include in the executive summary.
  - Send IDHS list of counties for which it will extract strategies to confirm all counties are covered.
- IDHS:
  - Confirm counties for which strategies should be documented.
  - Provide Polis with new text or FEMA responses by COB Thursday.

<td>3.3 Lawrence County has experienced many flash flooding events. These events usually result in culverts, bridges, and roadways washing out. We occasionally have water into homes or other structures if new construction has occurred changing the drainage pattern. It is common to have a 3 inch or more rain annually that results in flash flooding. Infrastructure Damage most of the time is able to be repaired in a 72 hour time period. Occasionally structures have to have more significant repair such as drying out thoroughly and replace of floor and wall surfaces. This sometimes has the owner displaced for 1 to 2 weeks. We have not had request for shelter for any of the flooding situations in the last 5 years. The inquires generally range in what kind of government assistance is available. We direct them to Red Cross and Salvation Army.</td>
<td></td>
</tr>

<td>Lawrence County has experienced at least two riot type situations with employee strikes. The Visteon Plant on West 16th Street in Bedford union workers were on strike for at least a week. Outsiders joined the strikers and fights and personal attacks on law enforcement were the result. A car was also set on fire in the middle of 16th Street which is also known as US 50. Local police started training and obtained riot gear as the lack of a contract settlement seemed imminent. In hind site some law enforcement consider themselves to be very fortunate as it could have been much worse with the outside force influence.</td>

<td>September 2016 a local gas station had a leak that permeated the city's sanitary sewer system. The local fire department had numerous calls throughout the week of gas fumes in residences and businesses. When fire officials checked with their meters it did not register or was very minimal. Fire officials knew something was occurring and collaborated with city utilities to track down the problem. In Friday Sept. 9th fire department was called to a rental home and the gas fumes were so great it did not register on the meter. Now the fire department had a location to backtrack from to find the source. The sanitary storm sewers were checked and there was a significant amount of gasoline running on top of the water in the sewer. It was determined that a local gasoline station who had recent work done on their underground tanks was the source. Emergency actions were taken, the public notified and extra fire personnel called in to respond to areas with gas fumes to determine concentration. IDEM responded and the owners of the gas station called in Indiana Spill Response and Recovery to...</td>

</tbody>
</table>

a transformer had to be brought in by helicopter. Businesses were generally closed and limited compared to today. People had to share food with neighbors and emergency responders. Lawrence County had another significant snow storm in 2003/2004 that resulted in 15+ inches of snow right at the Christmas holiday. The county highway and elected officials monitored the predicted storm and took mitigation steps to manage the storm and the snowfall did not reach levels where it could not be plowed off the highway. Business and industry ended with minimal interruption.
clear up the leak. A shelter led by the Red Cross was set up at the Local Boys and Girls Club for anyone who needed to evacuate their home. The resident of the rental home ended up staying in a local motel that was paid for by their landlord. We had one report of gasoline poisoning of a female from local hospital. EOC operations were set up at the Bedford Fire Department with Command established at the local gasoline station with the leak. Local police went door to door with flyers about what to do in case of gasoline odor in an area established by IDEM and the local Utility Manager. A tank was in place behind the service station with a vacuum truck for several weeks until the exact leak was found. Lawrence County has experienced other various spills such as gasoline and antifreeze. A farm implement accident with chemical spilling into a waterway and local fire department cleaned up the incident. A local quarry operation was allowing runoff into the waterway but quit once it was they were contacted of their error. Other various incidents such as paint spills on highway from a traffic incident have happened.

<td>4</td>
<td>On August 24, 2016 at approx. 2:30 PM an EF-2 tornado ripped through 6.2 miles of Montgomery County, mainly Linnsburg and along US 136 East between Mace and New Ross. The storm caused damage to homes (several demolished), corn silos, trees, fiber optic lines, electrical lines, and major crop loss. The duration of the actual tornado was only a few minutes, but the response and recovery lasted for up to a week- 10 days. Electricity was knocked out for up to 12 hours at some homes. This tornado complex is the same one that hit Kokomo after traveling through Clinton County. Resources were taxed,</td>

</table>
February. Waves of showers and thunderstorms moved across central Indiana on July 13 and into the early morning of July 14. Upper level features interacted with a surface front and plenty of moisture and instability to generate severe weather and heavy rains/flooding. Three tornadoes occurred in counties surrounding Montgomery. Widespread tree and power line damage occurred across central Indiana, and some locations received over 4 inches of rain. A few locations had hail as well. The heavy rain led to flooding in many areas.
