## ACKNOWLEDGEMENTS

The authors would like to express their appreciation to the other persons who contributed to this research project:

Anita Allen and Linda Terris for excellent field notes taken under most difficult circumstances in the cockpit of a circling airplane.

Mark McConahay, Bill Lingard, Jeff Redifer, Sandy Croll, and Tony Davis for photo interpretation, plotting, cataloging and record keeping.

Jeff Redifer for performance and dedication far beyond the call of duty.

Cathy Partenheimer for careful typing of the tables and manuscript.

## AERIAL PHOTOGRAPHIC SEARCH

### OVERVIEW OF METHODS CONSIDERED

The Indiana State Board of Health (ISBH) contracted with the Environmental Systems Application Center (ESAC) of the School of Public and Environmental Affairs (SPEA) to perform an aerial photographic survey for the purpose of locating unknown solid waste disposal facilities. Through consultation with the Solid Waste Management Section of ISBH a list of counties was compiled on which this aerial survey would be performed (Figure 1).

Preliminary investigations by ESAC staff revealed three methods for performing the aerial survey. Briefly, these were: (1) searching existing conventional aerial photography; (2) subcontracting with the EPA Environmental Photographic Interpretation Center (EPA/EPIC); and (3) ESAC staff flying over the assigned counties, locating waste disposal sites and photographing them with hand-held 35 mm cameras.

Each method was evaluated and ESAC staff concluded that the most feasible and cost effective method was the latter. This recommendation was put forth on March 4, 1980 in an ESAC report entitled Cost Analysis of Aerial Photographic Survey for the Open Dump Inventory.

Locating open dumps by searching conventional aerial photography proved to be unfeasible. The photography for Indiana is black and white and of a scale of 1:20,000 or smaller. There is not sufficient resolution to conclusively identify any solid waste disposal sites.

The EPA/EPIC had the capability to identify solid waste disposal sites using high resolution, false-color infrared aerial photography which is available only to federal agencies. These services could not be contracted for the Open Dump Inventory due to federal regulations concerning the return of federal funds.

A preliminary ESAC flight on December 14, 1979 verified that solid waste sites could be easily recognized from a low flying aircraft and that the aerial photographic search could be conducted in a cost-effective manner.

The aerial search as conducted by ESAC proved to be very effective at locating solid waste disposal sites. The techniques used in the aerial search will be detailed in this report in such a way as to allow other researchers to duplicate this technique for purposes of a future, similar study.

The aerial search methodology was developed by an on-going process of refinement from one flight to the next. After each flight the crew discussed the mission and improvements were suggested. Each suggestion was pragmatically evaluated and eventually the combination of procedures which produced the best results was adopted as the standard operating procedure.

#### ASSUMPTIONS

During the aerial search a qualitative judgement was needed to determine whether or not a site was actually an open dump and if so, whether or not to photograph it. The criteria evaluated were size and content.

The site was considered a dump if it contained waste material such as household garbage, rubbish, construction debris, ashes, slag or chemicals. Automobile junkyards were not considered dumps unless there was other waste disposal on the premises. Solid fill sites containing only soil, stone, masonry and construction rubble were not considered dumps. When the content of the site was unclear, but appeared to be waste materials, the site was photographed and recorded. In this way ESAC could provide the location and ISBH field personnel could make an on-site evaluation of whether the site is in violation of regulations.

The minimum size of a dump considered worth photographic documentation was 1,000 sq. ft. Smaller dumps than this were visible but too numerous to record.

The size of the dump was estimated from the air using the rule of thumb that 1,000 sq. ft. is the area required to park five automobiles.

In order to make optimal use of the time and resources available to conduct the flyover search, the ESAC staff prioritized the area within a given county. Flight plans were prepared on the assumption that the majority of dumps would be situated in or near centers of commerce, industry and residence. The flight plans were designed to thoroughly search the major incorporated community in the county, a 2-3 mile wide buffer zone around that community and the major transportation corridors (excluding interstate highways because of their limited access) leading to and from the community. Forest and agricultural lands which were remote from the center of population were not searched.

The validity of this assumption was tested on Vigo County. A hypothetical flight plan was prepared to search the city of Terre Haute and the area along the two major highways (U.S. 41 and U.S. 40). When the flyover search was done on April 5, 1980, the entire county was searched with equal thoroughness. The assumption of dump locations was found to be valid, at least for Vigo County, since no dumps were found outside of the hypothetical flight plan area.

Elkhart, St. Joseph and Marion Counties were also searched in their entirety and, again, the areas remote from major transportation routes and centers of commerce, industry and residence contained the fewest dumps.

#### AIRCRAFT

The aircraft for the aerial photographic search was a 1980 Cessna Skylane 182 owned by Torp Service and rented to ESAC for the purpose. This model Cessna is a high wing aircraft which allows the passengers an unobstructed view of the ground for searching and photographing. In addition to conventional radio and navigation equipment, this model was also equipped with distance measuring equipment (DME) and a transponder with an encoding altimeter. At the normal cruise speed, 130 knots, the maximum range was 750 statute miles.

The transponder emits an identification signal from the aircraft which is received by radar equipment. A transponder with an encoding altimeter emits a signal which also reports the instantaneous altitude of the plane. This feature of the aircraft was crucial to the success and safety of the mission when operating under positive radar control in the vicinities of major airports.

#### FLIGHT CREW

The flight crew consisted of four persons: the pilot in the left front seat, the navigator in the right front seat, the photographer in the right rear seat and the spotter in the left rear seat.

The pilot is concerned entirely with operation of the aircraft and communication. He flies according to the navigator's directions and maintains radio communication with air traffic controllers.

The navigator's chief responsibilities are to know the exact position of the aircraft at all times, and to give flight instructions to the pilot according to the flight plan. For example, typical instructions to the pilot may be, "make a left turn to heading 270°" or "make a tight right circle."

When a dump is spotted the navigator is informed of the location in direction and distance. The pilot is instructed to circle the site of a specified distance and the navigator marks the location and site number on his map. The navigator should be equipped with several maps (discussed later), a clipboard, dividers and a pencil.

The photographer searches for dumps on the right side of the aircraft and photographs them, usually taking 6-8 photographs of each dump.

The spotter searches for dumps on the left side of the airplane. The spotter is equipped with a clipboard and data sheets (Table 1) on which notes are recorded including site number, site description, altitude, time of day, cameras used, length of camera lens, frames exposed on each camera and often

a rough sketch of the site. When the photographer is changing film the spotter assists by unpacking and storing film and preparing the film roll identification sheet (Figure 3).

#### PHOTOGRAPHIC EQUIPMENT

ESAC owns two Nikon 35 mm cameras equipped with motor-drive film advance. Thus equipped, these cameras are capable of exposing several frames of film in rapid sequence. These cameras were fitted with a 24 mm, 50 mm or 75-205 mm zoom lens, the choice primarily depending on the altitude.

The film used was Kodachrome 64ASA on very bright days and Ektachrome 200 ASA on hazy days.

The shutter speed required to stop apparent motion when photographing from an airplane depends on speed, altitude and focal length of camera lens. At an air speed of 100 knots and an altitude of 2,000 ft. above ground, a shutter speed of 1/125 sec. will stop motion when using a 50 mm lens. A 1/ 500 sec. shutter speed is required for a 200 mm lens.

#### ALTITUDE

The altitude at which the aerial search is conducted determines the focal length of the camera lens. A higher altitude requires a longer lens to produce photographs of the same resolution. The open dump search had the best results flying at 2,000 ft. AGL (above ground level) and using a 50 mm lens on one camera and a 24 mm lens on the other. When flying at 3,000 ft. AGL a 50 mm lens and a 75-205 mm zoom lens were used.

An altitude of 2,000 ft. AGL corresponds to 2,400 ft. MSL (feet above mean sea level) in most of Vanderburgh County and 3,200 MSL in most of Wayne County.

Altitude affects visual acuity in two ways. Higher altitudes reduce visual resolution due to the increased distance between the ground and the eye. On the other hand, higher altitudes increase the breadth of vision, that is, the horizon

appears more distant. These two factors represent a trade-off and the flight crew judged 2,000 ft. AGL to represent an optimum between visual resolution and visual breadth.

When conducting the aerial search in the vicinity of controlled airports, an altitude was often assigned by the air traffic controllers. When this occurred the mission was continued at the assigned altitude, changing camera lenses as necessary.

#### AIRSPEED

Airspeed was adjusted according to the area being searched. Open portions of the county where dumps are few and widespread were searched at 130 knots (150 miles per hour: one nautical mile = 1.15 statute miles). Over urban and incorporated areas where dumps are more numerous, 100 knots (115 mph) was more effective. The pilot applied 10 degrees of wing flap as needed to further reduce airspeed to 90 knots over very crowded portions of the county.

Faster airspeeds allow a faster scan rate (area searched per unit time) but make photography of a site more difficult because less time is available for the crew to point out the site to each other and for the pilot to respond to instructions from the navigator.

#### MAPS

The navigator used four different types of maps. The map most frequently used was a county highway map, purchased from the Indiana State Highway Commission, which covered the entire county at a scale of 1" = 1 mile. These blue line maps were most useful in rural areas. A major shortcoming of these maps is that incorporated areas are shown only as a gray block defining the corporate boundaries, within which no roads, railroads, streams or other surface features are shown.

Topographic quadrangle maps from the U.S. Geological Survey (USGS) were used for navigation over large incorporated areas. These 1:24,000 (1" = 0.39 mile) scale maps are very detailed and accurate.

Quadrangle maps were useful for navigation except for the size and scale, as many as 12 of these maps being required to completely cover a county. At a speed of 130 knots, the plane would fly over the eight mile length covered by a quadrangle map in just over three minutes. The need to switch from one map to the next so frequently makes quadrangle maps inconvenient for use over rural areas.

When navigating from the point of flight origin to the target county or from one target county to the next, USGS  $1^{\circ} \times 2^{\circ}$  topographic maps, at a scale of 1:250,000 are useful.

The Federal Aviation Administration publishes sectional Aeronautical Charts for use by pilots flying under Visual Flight Regulations (VFR). These are available at scales of 1:500,000 and 1:1,000,000 and illustrate airports, air traffic control zones, radio and navigational signals, restricted flight zones, locations of towers and obstructions and other information pertinent to aerial navigation and communication. Selected information, including the locations of airports, tall towers and radio navigational beacons, was transferred from the aeronautical charts to the county and quadrangle maps and highlighted with colored ink. This was done so that the navigator would be aware of this information without switching from one map to another.

When searching an area in the vicinity of a controlled airport, a hand drawn summary map was prepared for the pilot which showed the airport, its control zone, other uncontrolled airports in the vicinity, the locations of VORTAC radio navigational beacons and the planned flight path of the aerial search. This map was used by the navigator to keep the pilot continually informed of the position of the plane relative to the airport and control zone.

#### FLIGHT PLAN

The breadth of vision from the airplane depended on altitude and weather conditions. With clear, cool weather and low haze (low humidity) a dump could

easily be detected with the unaided eye at a distance of 2.5 miles. If there was atmospheric haze or the dump was adjacent to or within forests, then 1.5 miles was the maximum distance of certain detection.

With these restrictions in mind, flight plans were laid out following the assumption that the flight crew can visually search the area within one mile on either side of the plane, without overlooking any potential sites. This meant that a two mile wide path was searched with each pass of the airplane.

Two separate aerial search patterns were employed. The north-south scan pattern was a series of passes, two miles apart, following section lines. For example, the search proceeded from north to south, moved two miles to the east, then searched from south to north, moved two miles east again, proceeded north to south, etc. and thus covered the search area with a series of switchbacks. The north-south scan covered 100% of the search area, but usually resulted in few data over remote agricultural and forest lands.

The other aerial search pattern, the transportation corridor search, was used to follow major transportation routes through the rural portions of the county.

When en route to or from assigned search counties (Figure 1) the flight path was directed, where convenient, over major transportation routes and communities in other counties. Several additional dump sites were located, at no extra expense, by this sort of planning.

#### PROCEDURES OF AERIAL SEARCH

The combined noises of wind, engine and radio often reached such a level that the flight crew had difficulty hearing each other speak in the cockpit of the airplane. For this reason, the navigator briefed the crew prior to each flight regarding counties to be searched, altitudes, estimated time of arrival, and other pertinent flight plans. Planning and briefing minimized the need for talking during the mission.

All flights originated from the Monroe County Airport, usually departing between 800 and 1200 hours. While en route to the target county the flight crew prepared its maps, cameras, and data sheets. Upon entering the county the navigator provided instructions to the pilot according to the flight plan.

The photographer and spotter searched the ground from the plane to one mile out on their respective sides. When a dump was spotted the navigator was informed of its approximate location by describing the direction and distance (e.g., "9 o'clock at 3/4 mile"). The navigator noted this location on the map and instructed the pilot to fly a clockwise circle of appropriate radius so the plane would circle the dump at a distance that allowed picture taking.

The dump was always circled in a clockwise direction because the navigator and photographer sat on the right side of the airplane and needed the best view of the site.

The photographer took from four to ten photographs as explained below. The spotter recorded the site number and other information concerning the cameras and location. The navigator marked the location and site number on the map and instructed the pilot when to return to the flight plan.

The procedure was planned to collect all photographs and data while circling each site only once. The entire process takes 60-90 seconds.

When changing film the pilots flew a standard circle with the aid of the turn-coordination instrument. This instrument enables flying the airplane in a 360° circle which will terminate directly over the origin (correcting for wind drift) and heading in the same direction. This standard rate turn allowed two minutes for the photographer to change film and "label" the new roll of film by photographing the clipboard with the film roll identification sheet (Figure 2).

#### PHOTOGRAPHY

Two types of photographs were taken of each dump site. Taking these photographs, was by necessity, closely coordinated with the position and degree of bank of the airplane.

Oblique photographs were taken at a distance of 0.5 to 1.0 mile from the site with the airplane in a shallow bank. Oblique photographs, often taken with a wide angle lens, showed the dump in proximity to surrounding landscape and landmarks and were used for post-flight verification of the dump site location. These were taken in either level flight or a shallow bank lest the wing obscure visibility.

Near vertical photographs were taken from a position more or less directly above the dump site. These photographs were taken with a longer lens to provide close up images of the dump site and its contents. A steep bank was needed for near vertical photographs, to provide a sharp image with a minimum of distortion.

Typically 2-5 shots of each type of photograph were taken as the plane circled the site. Figure 3 illustrates an idealized schematic of how a dump site was circled and photographed during the aerial search.

Photography from a moving airplane presents some particular complications which were corrected for as described below.

A shutter speed of 1/125 second was adequate to stop motion when 24 or 50 mm lenses were used. A 200 mm lens, however, enhanced the motion and a shutter speed of 1/500 second was necessary to prevent blur.

The distance to the subject was long enough such that the cameras were focused on infinity at all times, thus depth of field was unimportant. For these reasons wide aperture settings ( $f = 3.8$  to  $5.6$ ) were used to enable faster shutter speeds.

Each site was photographed with a range of apertures, bracketing the light meter reading, in order to have a gradient of exposures. This was particularly important where vegetation and bare ground appeared in the same frame. Otherwise the reflectance of the bare ground overloaded the light meter and the vegetated area was under-exposed and the bare ground over-exposed.

Photographing through the window of the airplane often caused glare problems. Glare was generally visible through the viewfinder and the photographer could avoid

it by tilting the camera to a different angle. Ideally, photographs were taken perpendicular to the window of the plane, avoiding the wing and landing gear while framing the dump site in the foreground. The optimum combination of aircraft bank position was short lived. Several frames were exposed in rapid sequence when the opportunity arose.

#### PHOTO INTERPRETATION

All of the information collected on dump sites during the aerial search was systematically evaluated by photo interpretation. The slides, the flight data sheets, the flight maps, and the 1:24,000 USGS topographic maps were examined concurrently, one site at a time, to ascertain concordance among all data. The photo interpreter examined the slides for obvious landmarks or land forms such as railroads, buildings, ponds, ditches, streams, hills and patterns of forestation. These features are also illustrated on topographic maps. By establishing the proximity of the dump site to these features, the location of the site was plotted accurately on the map.

Agreement was also confirmed between the direction of shadows in the slides and the time of day that the photos were taken. The physical location of the site must agree with other notes taken by the spotter.

The purpose of the photo interpretation process was to verify positively the location of the dump. Once this location was established it was described by latitude and longitude to the nearest second with the aid of a latitude-longitude scale (available from Indiana Geological Survey). The location was described by General Land Office Survey coordinates by range, township, section, 1/4 section and 1/16 section and also by a brief description of adjacent roads and landmarks.

#### RECORDS

The Open Dump Inventory (ODI) flyover search generated a large data base in the form of slides and descriptive information on dump sites. During the project, these data were recorded and kept using the following formats:

When a new roll of film was loaded into the camera, a film roll identification sheet (Figure 2) was filled out and photographed in the cockpit of the airplane. This became a "tag" by which every roll of film was positively identified when it returned from the processors.

During the flights, the spotter recorded the information pertinent to each site on data forms prepared for the purpose (Table 1). Information recorded included film roll number, the frame number on that roll, site number, a description or sketch of the site, camera and lens in use, time, altitude (MSL) and other notes as appropriate.

When each roll of film was returned from the processor each slide was labeled with flight number, roll number, slide number and site number. The slides were stored in transparent plastic slide envelopes which were kept in three-ring binders. The ESAC in-house slide catalog was indexed by flight number for logistic reasons. After photo interpretation was completed, and before presenting the slide collection to ISBH, the catalog was reorganized into a system indexed by county.

As each site was photo interpreted, the descriptive information was compiled into a computerized data file by Community and Institutional Research Services (CAIRS) at Indiana University, South Bend, Indiana. This information is also found in Table 3.

## FINDINGS AND RESULTS

### AERIAL PHOTOGRAPHIC SEARCH

The aerial search was conducted in 19 flights, each of 3-6 hours duration, over 35 Indiana counties. During these flights 636 dump sites were recognized, photographed and documented. A tabular summary of the counties flown appears in Table 2. The dump sites documented are tabulated by county in Table 3, along with descriptors, locators, the number of slides taken and the dates.

### DATA IMPLICATIONS TO SITE EVALUATIONS

The information compiled from the ESAC aerial search can be considered absolute. The slides constitute proof that a dump actually exists and the correct location is verifiable from the slides.

The locations of the dump sites have been provided in three separate ways. All sites were plotted on county highway maps ( $1'' = 1$  mile). General Land Office (GLO) survey coordinates have also been provided (Table 3). These are range, township, section, 1/4 section and 1/16 section. Finally, latitude and longitude have been reported to the nearest second.

For reasons explained below, the latitude and longitude data are the most accurate and the ESAC staff recommends that ISBH use these data to establish the dump locations for their in-house purposes. ESAC provided ISBH a latitude-longitude overlay grid identical to the one used by ESAC to make the original measurements on the topographic maps. ISBH can use this grid, the latitude-longitude data and their own topographic maps to accurately plot the dump site locations.

### DATA LIMITATIONS AND SOURCES OF ERROR

The aerial search dump sites were plotted on county highway maps (scale,  $1'' = 1$  mile) using 1/4 inch black triangles. The precision of the plotting was limited by scale of the maps and the size of the plotting medium. The uncertainty in the map locations is roughly the area covered by the triangles or 1/4 mile.

The General Land Office survey coordinates of dump locations are listed down to 1/16 section which is a 1/4 mile x 1/4 mile square. The uncertainty of a dump location using these coordinates is then, 1/4 mile.

Latitude and longitude are reported for each dump location to the nearest second. One second of latitude is, by definition, 1/60 of a nautical mile or roughly 100 ft. The uncertainty in measuring latitude and longitude then is  $\pm 100$  ft. There was, however, additional uncertainty when the photo interpreter located the sites on the topographic map. All sources of error included the maximum uncertainty for any particular site is  $\pm 400$  ft. and most sites have less uncertainty than that.

The possibility that major dump sites were undetected within the area searched is remote but real. It was not possible to see the ground directly below the plane so there was a 0.10 mile wide path in which a dump would have been unseen. Since the flight plan was based on a scan width of two miles, the 0.10 mile path which could not be seen represents a  $0.10/2 \text{ mile} \times 100\% = 5\%$  probability that dump sites may have been overlooked within the area searched on a given flight.

The contents of a dump could be somewhat evaluated by the naked eye when flying over the site. The observed contents were not recorded on a site by site basis, however, because it would have doubled the time required to document the site (i.e., flying two circles around the site rather than one) and the large number of dump sites encountered prohibited this. The photo interpreters evaluated the contents of each dump when the slides were reviewed and assigned one of the type of material categories on the dump site reporting sheet (Table 3). This evaluation was based on recognition of the contents as shown by the slides and the surrounding land use.

#### ACCESS TO DATA AND SLIDE CATALOG

ISBH can find information on the aerial search dump sites in each of four places. These are the site list (Table 3), the computer data file (under the appropriate respondent code number), the maps provided and the slide catalog.

Each dump site was assigned a four digit identification number. The first two digits designate the county in which the site is located. The latter two digits designate the site number within that county. For example, 02-15 identifies Allen County, Site 15 on the maps, lists and slides.

Table 3 tabulates all sites located by the aerial search in numerical order and lists the county code, site number, number of slides, date, type of material category, size category, USGS quadrangle name, range, township, section 1/4 section and 1/16 section, north latitude, west longitude and written directions to the site. The computer data file stored the same information as Table 3 except the directions to the site.

Each slide of the slide catalog contains a six digit identification number. The first four digits correspond to county code and site number as above and the last two digits identify the slide number for that particular site.

The aerial search sites were plotted onto county highway maps (scale: 1" = 1 mile) with solid black triangles. Each triangle was labeled with a two digit site number. This site number is the same as was used in the site list, the computer data file and the slide catalog. The aerial search map has the search area indicated by a crosshatch pattern.

The dump sites which were reported from the mail survey data search and the file data search, were also plotted on identical maps. Mail survey sites are represented by an orange circle. Permitted landfills and permitted closed landfill are represented by solid black squares and open black squares respectively.

All of the dump sites from the aerial search maps, the survey data search maps and the file data search maps were consolidated onto a Mylar transparency. There is one transparency for each county. The transparencies have an outline of the county boundary and are the same scale as the county maps (1" = 1 mile). This allows the transparencies to be superimposed on any of the other maps of the same county.

ERRATA

The following entries are corrections to the aerial search data in the CAIRS computer file. These corrections have been made in Table 3.

<u>Site</u>	<u>Reads</u>	<u>Should Read</u>

PART II

DATA SEARCH FOR OPEN DUMP INVENTORY  
REVIEW OF EXISTING RECORDS

By

Dr. Wayne F. Echelberger  
Ronald E. Segert

Indiana University  
School of Public and Environmental Affairs  
Environmental Systems Application Center

Prepared For

Indiana State Board of Health  
Solid Waste Management Section

The contract between the Indiana State Board of Health (ISBH) and Indiana University School of Public and Environmental Affairs (SPEA) for the Data Search for Open Dump Inventory Project required that SPEA staff review existing records of the ISBH and compile a list of known nonpermitted solid waste disposal sites in Indiana.

The closed nonpermitted solid waste disposal sites are listed by county in Table 1 along with geographic descriptors. The operating nonpermitted solid waste disposal sites are listed in Table 2.

These sites have been plotted on county highway maps (scale: 1" = 1 mile) using open black square and solid black squares for closed and operating sites, respectively.
